18 PRAM3_FCCU_ALARM_EN	Enable bit for enabling the fault monitoring at FCCU NCF 2 for the fault: PRAM3 safety alarm. This alarm is set on faulty SRAM3 read or read modify error. 0b - No safety alarm indicated by PRAM3. 1b - Safety alarm indicated by PRAM3.
17	Enable bit for enabling the fault monitoring at FCCU NCF 2 for the fault: Multi bit ECC error from SRAM3.

Table continues on the next page...

Table continued from the previous page...

Field	Function
PRAM3_ECC_ERR_EN	0b - No multi-bit ECC error. 1b - Multi-bit ECC error.
16 FLASH1_ECC_ERR_EN	Enable bit for enabling the fault monitoring at FCCU NCF 3 for the fault: ECC error from Flash Controller1. This alarm indicates that the flash controller1 detected an error in the address ECC manipulation logic through EDC. 0b - No ECC error from flash controller1. 1b - ECC error from flash controller1.
15 —	Reserved
14 FLASH1_RST_ERR_EN	Enable bit for enabling the fault monitoring at FCCU NCF 3 for the fault: Flash1 reset error . This error indication is set when flash1 encounters errors during its reset reads. 0b - No flash1 reset error indicated. 1b - Flash1 reset error indicated.
13 FLASH1_REF_ERR_EN	Enable bit for enabling the fault monitoring at FCCU NCF 3 for the fault: Flash1 reference current loss or read voltage error while prevoius read. 0b - No reference current loss or read voltage error while previous read. 1b - Reference current loss or read voltage error while previous read.
12 FLASH1_ADDR_ENC_ERR_EN	Enable bit for enabling the fault monitoring at FCCU NCF 3 for the fault: Flash1 address encode error. In address decoding, if multiple or no address line is selected, FMU reports address encode error. 0b - No address encode error in flash1. 1b - Address encode error in flash1.
11 FLASH1_EDC_ERR_EN	Enable bit for enabling the fault monitoring at FCCU NCF 3 for the fault: Flash1 ECC correction error through EDC reported by FMU. 0b - No EDC after ECC error reported in flash1. 1b - EDC after ECC error reported in flash1.
10 PF1_1_DATA_ECC_ERR_EN	Enable bit for enabling the fault monitoring at FCCU NCF 3 for the fault: Flash3 data ECC uncorrectable error. The path is from FMU to PFLASH controller to ERM to FCCU. 0b - No uncorrectable error reported in flash controller port 3 data memory by FMU. 1b - Uncorrectable error reported in flash controller port 3 data memory by FMU.
9 PF1_1_CODE_ECC_ERR_EN	Enable bit for enabling the fault monitoring at FCCU NCF 3 for the fault: Flash3 code ECC uncorrectable error. The path is from FMU to PFLASH controller to ERM to FCCU. 0b - No uncorrectable error reported in flash controller port 3 code memory by FMU. 1b - Uncorrectable error reported in flash controller port 3 code memory by FMU.
8	Enable bit for enabling the fault monitoring at FCCU NCF 3 for the fault: Flash2 data ECC uncorrectable error. The path is from FMU to PFLASH controller to ERM to FCCU.

Table continues on the next page...

Table continued from the previous page...

Field	Function
PF1_0_DATA_ECC_ERR_EN	0b - No uncorrectable error reported in flash controller port 2 data memory by FMU. 1b - Uncorrectable error reported in flash controller port 2 data memory by FMU.
7 PF1_0_CODE_ECC_ERR_EN	Enable bit for enabling the fault monitoring at FCCU NCF 3 for the fault: Flash2 code ECC uncorrectable error. The path is from FMU to PFLASH controller to ERM to FCCU. 0b - No uncorrectable error reported in flash controller port 2 code memory by FMU. 1b - Uncorrectable error reported in flash controller port 2 code memory by FMU.
6 AES_RESULT_DID_SAFETY_ERR_EN	Enables bit for enabling the fault monitoring at FCCU NCF 2 for the fault: AES RESULT DMA DID error. 0b - AES RESULT DMA DID error not enabled. 1b - AES RESULT DMA DID error enabled.
5 AES_FEED_DID_SAFETY_ERR_EN	Enables bit for enabling the fault monitoring at FCCU NCF 2 for the fault: AES FEED DMA DID error. 0b - AES FEED DMA DID error not enabled. 1b - AES FEED DMA DID error enabled.
4 AES_KP_CRC_SAFETY_ERR_EN	Enables bit for enabling the fault monitoring at FCCU NCF 2 for the fault: AES Key Property CRC Safety Error. 0b - AES key-property CRC safety error not enabled. 1b - AES key-property CRC safety error enabled.
3 AES_RESULT_DMA_TCD_ADDR_ECC_ERR_EN	Enables bit for enabling the fault monitoring at FCCU NCF 2 for the fault: AES ACCEL RESULT DMA_TCD address ECC error. 0b - No address error reported in AES ACCEL RESULT DMA_TCD memory. 1b - Address error reported in AES ACCEL RESULT DMA_TCD memory.
2 AES_RESULT_DMA_TCD_ECC_ERR_EN	Enables bit for enabling the fault monitoring at FCCU NCF 2 for the fault: AES ACCEL RESULT DMA_TCD memory uncorrectable ECC error. 0b - No uncorrectable error reported in AES ACCEL RESULT DMA_TCD memory. 1b - Uncorrectable error reported in AES ACCEL RESULT DMA_TCD memory.
1 AES_FEED_DMA_TCD_ADDR_ECC_ERR_EN	Enables bit for enabling the fault monitoring at FCCU NCF 2 for the fault: AES ACCEL FEED DMA_TCD address ECC error. 0b - No address error reported in AES ACCEL FEED DMA_TCD memory. 1b - Address error reported in AES ACCEL FEED DMA_TCD memory.
0 AES_FEED_DMA_TCD_ECC_ERR_EN	Enables bit for enabling the fault monitoring at FCCU NCF 2 for the fault: AES ACCEL FEED DMA_TCD memory uncorrectable ECC error. 0b - No uncorrectable error reported in AES ACCEL FEED DMA_TCD memory. 1b - Uncorrectable error reported in AES ACCEL FEED DMA_TCD memory.

Fields

Field	Function
31 SAI1_DBG_DIS_CM7_3	Specifies whether SAI1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - SAI1 enters debug mode when CM7_3 enters debug mode. 1b - SAI1 remains functional and is not impacted when CM7_3 enters debug mode.
30 SAI0_DBG_DIS_CM7_3	Specifies whether SAI0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - SAI0 enters debug mode when CM7_3 enters debug mode. 1b - SAI0 remains functional and is not impacted when CM7_3 enters debug mode.
29 FLEXCAN5_DBG_DIS_CM7_3	FlexCAN5 Debug Disable For Cortex-M7_3 Specifies whether FlexCAN5 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - FlexCAN5 enters debug mode when CM7_3 enters debug mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - FlexCAN5 remains functional and is not impacted when CM7_3 enters debug mode.
28 FLEXCAN4_DBG_DIS_CM7_3	FlexCAN4 Debug Disable For Cortex-M7_3 Specifies whether FlexCAN4 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - FlexCAN4 enters debug mode when CM7_3 enters debug mode. 1b - FlexCAN4 remains functional and is not impacted when CM7_3 enters debug mode.
27 FLEXCAN3_DBG_DIS_CM7_3	FlexCAN3 Debug Disable For Cortex-M7_3 Specifies whether FlexCAN3 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - FlexCAN3 enters debug mode when CM7_3 enters debug mode. 1b - FlexCAN3 remains functional and is not impacted when CM7_3 enters debug mode.
26 FLEXCAN2_DBG_DIS_CM7_3	FlexCAN2 Debug Disable For Cortex-M7_3 Specifies whether FlexCAN2 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - FlexCAN2 enters debug mode when CM7_3 enters debug mode. 1b - FlexCAN2 remains functional and is not impacted when CM7_3 enters debug mode.
25 FLEXCAN1_DBG_DIS_CM7_3	FlexCAN1 Debug Disable For Cortex-M7_3 Specifies whether FlexCAN1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - FlexCAN1 enters debug mode when CM7_3 enters debug mode. 1b - FlexCAN1 remains functional and is not impacted when CM7_3 enters debug mode.
24 FLEXCAN0_DBG_DIS_CM7_3	FlexCAN0 Debug Disable For Cortex-M7_3 Specifies whether FlexCAN0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - FlexCAN0 enters debug mode when CM7_3 enters debug mode. 1b - FlexCAN0 remains functional and is not impacted when CM7_3 enters debug mode.
23	FlexIO Debug Disable For Cortex-M7_3 Specifies whether FlexIO enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
FLEXIO_DBG_DIS_CM7_3	Write 1 to this field to disable debug. 0b - FlexIO enters debug mode when CM7_3 enters debug mode. 1b - FlexIO remains functional and is not impacted when CM7_3 enters debug mode.
22 LPI2C1_DBG_DIS_CM7_3	LPI2C1 Debug Disable For Cortex-M7_3 Specifies whether LPI2C1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - LPI2C1 enters debug mode when CM7_3 enters debug mode. 1b - LPI2C1 remains functional and is not impacted when CM7_3 enters debug mode.
21 LPI2C0_DBG_DIS_CM7_3	LPI2C0 Debug Disable For Cortex-M7_3 Specifies whether LPI2C0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - LPI2C0 enters debug mode when CM7_3 enters debug mode. 1b - LPI2C0 remains functional and is not impacted when CM7_3 enters debug mode.
20 LPSPI5_DBG_DIS_CM7_3	LPSPI5 Debug Disable For Cortex-M7_3 Specifies whether LPSPI5 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - LPSPI5 enters debug mode when CM7_3 enters debug mode. 1b - LPSPI5 remains functional and is not impacted when CM7_3 enters debug mode.
19 LPSPI4_DBG_DIS_CM7_3	LPSPI4 Debug Disable For Cortex-M7_3 Specifies whether LPSPI4 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - LPSPI4 enters debug mode when CM7_3 enters debug mode. 1b - LPSPI4 remains functional and is not impacted when CM7_3 enters debug mode.
18 LPSPI3_DBG_DIS_CM7_3	LPSPI3 Debug Disable For Cortex-M7_3 Specifies whether LPSPI3 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - LPSPI3 enters debug mode when CM7_3 enters debug mode. 1b - LPSPI3 remains functional and is not impacted when CM7_3 enters debug mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
17 LPSPI2_DBG_DIS_CM7_3	LPSPI2 Debug Disable For Cortex-M7_3 Specifies whether LPSPI2 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - LPSPI2 enters debug mode when CM7_3 enters debug mode. 1b - LPSPI2 remains functional and is not impacted when CM7_3 enters debug mode.
16 LPSPI1_DBG_DIS_CM7_3	LPSPI1 Debug Disable For Cortex-M7_3 Specifies whether LPSPI1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - LPSPI1 enters debug mode when CM7_3 enters debug mode. 1b - LPSPI1 remains functional and is not impacted when CM7_3 enters debug mode.
15 LPSPI0_DBG_DIS_CM7_3	LPSPI0 Debug Disable For Cortex-M7_3 Specifies whether LPSPI0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - LPSPI0 enters debug mode when CM7_3 enters debug mode. 1b - LPSPI0 remains functional and is not impacted when CM7_3 enters debug mode.
14 PIT2_DBG_DIS_CM7_3	PIT2 Debug Disable For Cortex-M7_3 Specifies whether PIT2 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - PIT2 enters debug mode when CM7_3 enters debug mode. 1b - PIT2 remains functional and is not impacted when CM7_3 enters debug mode.
13 PIT1_DBG_DIS_CM7_3	PIT1 Debug Disable For Cortex-M7_3 Specifies whether PIT1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - PIT1 enters debug mode when CM7_3 enters debug mode. 1b - PIT1 remains functional and is not impacted when CM7_3 enters debug mode.
12 PIT0_DBG_DIS_CM7_3	PIT0 Debug Disable For Cortex-M7_3 Specifies whether PIT0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - PIT0 enters debug mode when CM7_3 enters debug mode. 1b - PIT0 remains functional and is not impacted when CM7_3 enters debug mode.
11 STM1_DBG_DIS_CM7_3	STM1 Debug Disable For Cortex-M7_3 Specifies whether STM1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - STM1 enters debug mode when CM7_3 enters debug mode. 1b - STM1 remains functional and is not impacted when CM7_3 enters debug mode.
10 STM0_DBG_DIS_CM7_3	STM0 Debug Disable For Cortex-M7_3 Specifies whether STM0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - STM0 enters debug mode when CM7_3 enters debug mode. 1b - STM0 remains functional and is not impacted when CM7_3 enters debug mode.
9 SWT1_DBG_DIS_CM7_3	SWT1 Debug Disable For Cortex-M7_3 Specifies whether SWT1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - SWT1 enters debug mode when CM7_3 enters debug mode. 1b - SWT1 remains functional and is not impacted when CM7_3 enters debug mode.
8 SWT0_DBG_DIS_CM7_3	SWT0 Debug Disable For Cortex-M7_3 Specifies whether SWT0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - SWT0 enters debug mode when CM7_3 enters debug mode. 1b - SWT0 remains functional and is not impacted when CM7_3 enters debug mode.
7 RTC_DBG_DIS_CM7_3	RTC Debug Disable For Cortex-M7_3 Specifies whether RTC enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - RTC enters debug mode when CM7_3 enters debug mode. 1b - RTC remains functional and is not impacted when CM7_3 enters debug mode.

Table continues on the next page...

Field	Function
6 eMIOS2_DBG_DIS_CM7_3	Specifies whether eMIOS2 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - eMIOS2 enters debug mode when CM7_3 enters debug mode. 1b - eMIOS2 remains functional and is not impacted when CM7_3 enters debug mode.
5 eMIOS1_DBG_DIS_CM7_3	Specifies whether eMIOS1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - eMIOS1 enters debug mode when CM7_3 enters debug mode. 1b - eMIOS1 remains functional and is not impacted when CM7_3 enters debug mode.
4 eMIOS0_DBG_DIS_CM7_3	eMIOS0 Debug Disable For Cortex-M7_3 Specifies whether eMIOS0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - eMIOS0 enters debug mode when CM7_3 enters debug mode. 1b - eMIOS0 remains functional and is not impacted when CM7_3 enters debug mode.
3 LCU1_DBG_DIS_CM7_3	LCU1 Debug Disable For Cortex-M7_3 Specifies whether LCU1 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. If this field = 0, LCU1 enters Debug mode, and if this field = 1, LCU1 remains functional. Write 1 to this field to disable debug. 0b - LCU1 enters debug mode when CM7_3 enters debug mode. 1b - LCU1 remains functional and is not impacted when CM7_3 enters debug mode.
2 LCU0_DBG_DIS_CM7_3	LCU0 Debug Disable For Cortex-M7_3 Specifies whether LCU0 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. If this field = 0, LCU0 enters Debug mode, and if this field = 1, LCU0 remains functional. Write 1 to this field to disable debug. 0b - LCU0 enters debug mode when CM7_3 enters debug mode. 1b - LCU0 remains functional and is not impacted when CM7_3 enters debug mode.
1 FCCU_DBG_DIS_CM7_3	FCCU Debug Disable For Cortex-M7_3 Specifies whether FCCU enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. If this field = 0, FCCU enters Debug mode, and if this field = 1, FCCU remains functional. Write 1 to this field to disable debug.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - FCCU enters debug mode when CM7_3 enters debug mode. 1b - FCCU remains functional and is not impacted when CM7_3 enters debug mode.
0 EDMA_DBG_DIS_CM7_3	EDMA Debug Disable For Cortex-M7_3 Specifies whether eDMA enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. If this field = 0, eDMA enters Debug mode, and if this field = 1, eDMA remains functional. Write 1 to this field to disable debug. 0b - EDMA enters debug mode when CM7_3 enters debug mode. 1b - EDMA remains functional and is not impacted when CM7_3 enters debug mode.

38.2.47 Read Write GPR On Destructive Reset 20 (DCMRWD20)

Offset

Register	Offset
DCMRWD20	54Ch

Function
This is a readable and writable general purpose register which gets reset on destructive reset.

Diagram

20-5 —	Reserved
4 SWT2_DBG_DIS_CM7_3	SWT2 Debug Disable For Cortex-M7_3 Specifies whether SWT2 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - SWT2 enters debug mode when CM7_3 enters debug mode. 1b - SWT2 remains functional and is not impacted when CM7_3 enters debug mode.
3 STM2_DBG_DIS_CM7_3	STM2 Debug Disable For Cortex-M7_3 Specifies whether STM2 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - STM2 enters debug mode when CM7_3 enters debug mode. 1b - STM2 remains functional and is not impacted when CM7_3 enters debug mode.
2 FLEXCAN7_DBG_DIS_CM7_3	Specifies whether FLEXCAN7 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - FLEXCAN7 enters debug mode when CM7_3 enters debug mode. 1b - FLEXCAN7 remains functional and is not impacted when CM7_3 enters debug mode.
1 FLEXCAN6_DBG_DIS_CM7_3	FlexCAN6 Debug Disable For Cortex-M7_3 Specifies whether FlexCAN6 enters Debug mode or remains functional and unimpacted when the Cortex-M7_3 core enters Debug mode. Write 1 to this field to disable debug. 0b - FlexCAN6 enters debug mode when CM7_3 enters debug mode. 1b - FlexCAN6 remains functional and is not impacted when CM7_3 enters debug mode.
0 —	Reserved

38.2.48 Read Write GPR On Functional Reset 1 (DCMRWF1)

Offset

Register	Offset
DCMRWF1	600h

Function

Contains information related to:

- Voltage dividers, LFAST clocks, and supply voltage monitoring.
- I/O configurations.

This field resets after functional reset 1.

Field	Function
19 MAC_SB_END_CTRL	MAC Sideband Data Endianness Control 0b - The MAC sideband data is transferred in little-endian mode. 1b - The MAC sideband data is transferred in big-endian mode.
18 PMIC_PGOOD_HNDSHK_BYP	Controls the PMIC_PGOOD handshake with the external Power Management IC (PMIC) while standby exit. 0b - The standby exit proceeds only when the active edge (as per DCMRWF2[PGOOD_POLARITY] configuration) is detected on the PGOOD signal. 1b - The PMIC_PGOOD handshake with the PMIC is bypassed.
17 —	Reserved
16 STANDBY_IO_CONFIG	Standby I/O Configuration Controls the IO state in the standby mode. This bit needs to be written both at the standby entry as well as standby exit as per the below description. 0b - Must be written as 0 before IO configurations are done in standby entry sequence. 1b - Must be written as 1 after IO configurations are done on standby exit.
15 VDD_HV_B_IO_CTRL_LATCH	VDD_HV_B I/O Control Latch Controls the IO controls (SRC, DSE, PKE, PUS, PUE, IBE and OBE) latching in low frequency RUN mode to reduce power consumption on VDD_HV_B domain pins. The pad output path is functional as usual. **NOTE** This field must remain 0, except in FIRC 3 MHz and FIRC 187.5 kHz operation modes. 0b - VDD_HV_B domain pins function as normal. 1b - The IO controls of VDD_HV_B domain pins are latched.

24 PLL1_LOL_RST_EN	PLL1 LOL Reset Enable Controls the functional reset or interrupt behavior of the PLL1 LOL event. 0b - PLL1 LOL event results in an interrupt 1b - PLL1 LOL event results in a reset
23-22 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
21 PGOOD_POLARITY	PGOOD Signal Edge Polarity See the PMIC documentation before performing this configuration. **NOTE** PGOOD_POLARITY configuration is valid only if PMIC_PGOOD_HNDSHK_BYP is set as 1'0b. 0b - Rising egde. PGOOD signal is considered active while it sees a transitioning edge from active low state to active high state. 1b - Falling egde. PGOOD signal is considered active while it sees a transitioning edge from active high state to active low state.
20 —	Reserved
19 —	Reserved
18 —	Reserved
17 VIRT_WRAP_IPSYNC_BYPASS	VIRT_WRAPPER IPSYNC Bypass Bypasses the VIRT_WRAPPER IPSYNC. **NOTE** The VIRT_WRAPPER IPSYNC can alternatively also be bypassed using UTEST_MISC[12]. See UTEST client description for details. 0b - Enables 1b - Bypasses
16 HSE_GSKT_BYPASS	HSE_B Gasket Bypass Enables the HSE_B IAHB gasket behavior out of Standby mode. • If you write 0 to this field, the DCF client controls the HSE_B IAHB gasket bypass configuration. The system must continue to run on FIRC, and if intended to run on PLL, a functional reset must be asserted. • If you write 1 to this field, the HSE_B IAHB gasket is bypassed out of standby. 0b - Not bypassed 1b - Bypassed
15-13 SUPPLY2_MON_SEL	Supply 2 Monitoring Select Selects the source of voltage that ADC uses for supply monitoring.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The SUPPLY2_MON_SEL configurations are effective only when SUPPLY2_MON_EN is 1. 000b - VDD2P5_PLL2 001b - VDD1P1_PLL2 010b - Reserved 011b - Reserved
12 SUPPLY2_MON_EN	Supply 2 Monitoring Enable Enables supply voltage that ADC monitors to makes use of another ANAMUX. 0b - Disables 1b - Enables
11 SAI_MCLK2_SEL	SAI MCLK2 Select Controls the SAI_MCLK2 clk source. 0b - FXOSC is the SAI_MCLK2 clock source. 1b - PLL_AUX_PHI1 is the SAI_MCLK2 clock source.
10-9 MAC_TX_RX_CLK_MUX_BYPASS	MAC TX RX CLK MUX BYPASS Bypasses the MAC_TX_CLK and MAC_RX_CLK sources depending on DCMRWF3[15:13] configuration. 00b - The MAC_RX_CLK in the configuration if DCMRWF3[14:13] is 2'b00 is derived from MC_CGM_MUX7. The MAC_TX_CLK in the configuration if DCMRWF3[15] is 1'b0 is derived from MC_CGM_MUX8. 01b - The MAC_RX_CLK in the configuration if DCMRWF3[14:13] is 2'b00 is derived from RMII_CLK DIV2. The MAC_TX_CLK in the configuration if DCMRWF3[15] is 1'b0 is derived from RMII_CLK DIV2. 10b - The MAC_RX_CLK in the configuration if DCMRWF3[14:13] is 2'b00 is derived from RMII_CLK DIV20. The MAC_TX_CLK in the configuration if DCMRWF3[15] is 1'b0 is derived from RMII_CLK DIV20. 11b - The MAC_RX_CLK in the configuration if DCMRWF3[14:13] is 2'b00 is inactive/disabled. The MAC_TX_CLK in the configuration if DCMRWF3[15] is 1'b0 is inactive/disabled.
8 PMOS_CTRL_GPIO_DATA	PMOS Control GPIO Data Controls the data-out from the PMOS_CTRL pad when PMC.CONFIG[LMSMPSEN] is 0. PMOS_CTRL_GPIO_DATA is not impacted if PMC.CONFIG[LMSMPSEN] is 1. 0b - Data is 0 1b - Data is 1
7-6 —	Reserved

38.2.52 Read Write GPR On Functional Reset 5 (DCMRWF5)

Offset

Register	Offset
DCMRWF5	610h

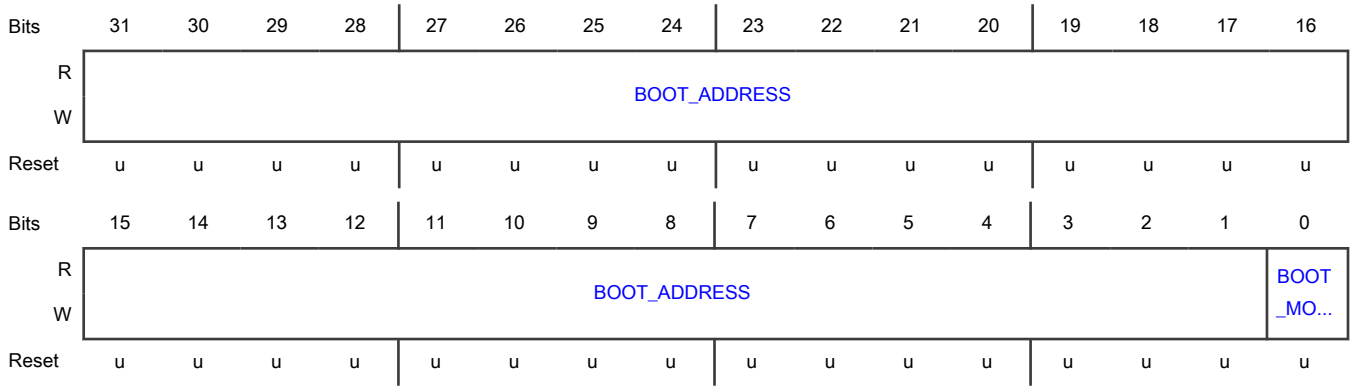
Function

Contains boot address and boot mode.

This register resets after functional reset 5.

The reset value of this register is undefined on reset and is loaded from the flash memory contents at the end of the reset sequence.

Diagram



Fields

Field	Function
31-1 BOOT_ADDRESS	Boot Address Specifies the Cortex-M7_0 base address of the vector table to be used after exiting Standby mode (only to be considered in Fast Standby mode).
0 BOOT_MODE	Boot Mode Selects the type of Boot mode after exiting Standby mode. 0b - Normal 1b - Fast Standby

38.2.53 Read-Only GPR On PMCPOR Reset 1 (DCMROPP1)

Offset

Register	Offset
DCMROPP1	700h

Function

Resets after PMCPOR reset 1 and captures the status of the functional reset sequence process when POR_WDG overflows.

Diagram

38.2.56 Read-Only GPR On PMCPOR Reset 4 (DCMROPP4)

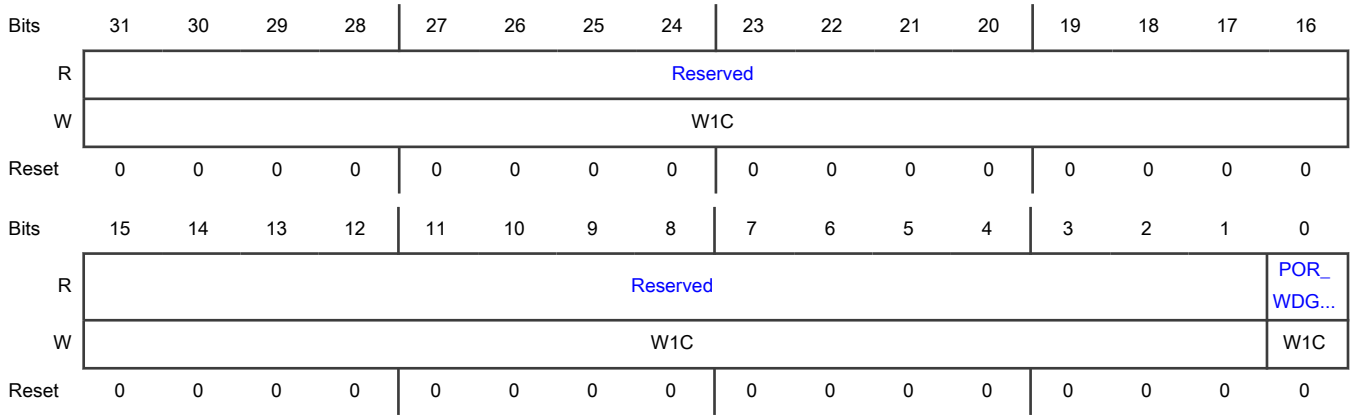
Offset

Register	Offset
DCMROPP4	70Ch

Function

Resets after PMCPOR reset 4 and captures the POR_WDG reset event if POR_WDG initiates a POR sequence.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 POR_WDG_STAT96	POR_WDG Status 96 Specifies the status of POR_WDG. If this field = 1, it indicates that a stuck scenario is detected and the chip POR event is raised. See POR_WDG_STAT[95:0] for the chip status when POR_WDG overflows. 0b - Inactive 1b - Active

Chapter 39
Device Configuration Module (DCM)

39.1 Overview

39.1.1 Block diagram

This figure is a pictorial representation of DCM

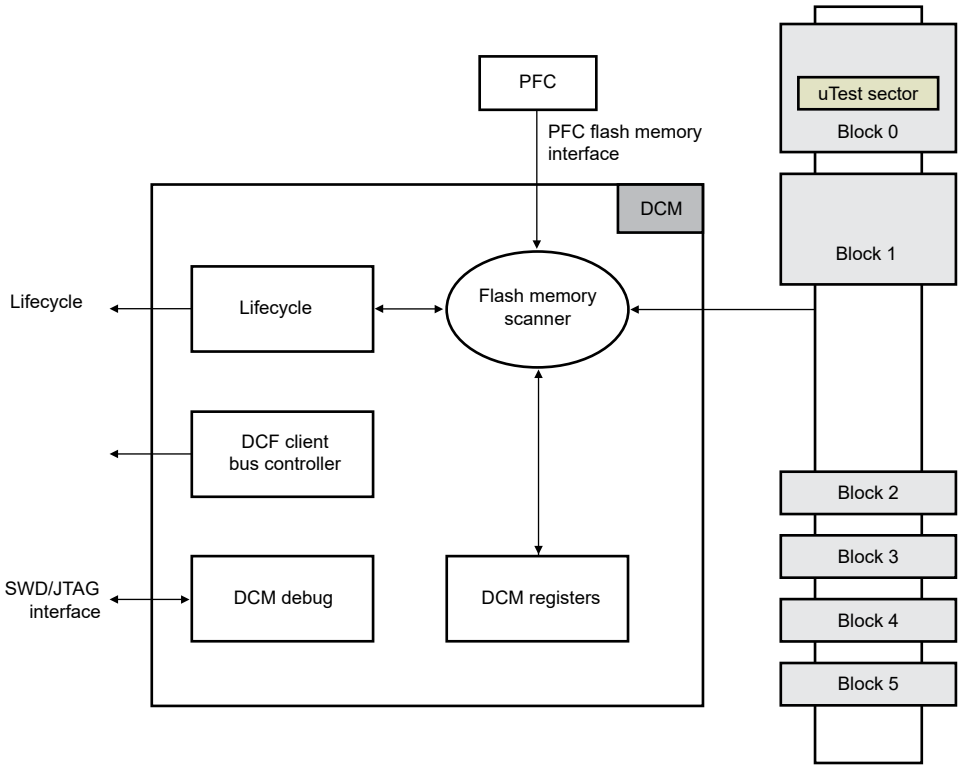


Figure 160. DCM block diagram

DCM controls:

- LC
- DCF client population
- Debug authorization (Export Control mode)

The module also establishes a RoT for the chip by parsing the master root key and other security records.

39.1.2 Features

- Scans flash memory and configures the system for:
  - LC detection
  - DCF records configuration using flash memory
- Allows debug features for flash memory content and the chip

- Provides debug enable control
- Provides a valid boot address detection
- Enables the DCF client to be writable via the IPS bus
- Parametrizes control to mask a set of DCF client chip select
- Supports temporary advancement of the LC
- Controls chip debug enablement

39.2 Functional description

DCM provides information about the current state and configuration of the system that you could use to:

- Configure the application software.
- Debug the system.

39.2.1 Modes of operation

DCM operates identically in all system modes of operation.

39.2.2 DCF mechanism

The DCF mechanism handles chip parameter settings via the OTP flash memory.

You can store a series of DCF records in flash memory, and each record is 64 bits in length. The chip processes these records during the system reset sequence before the CPU leaves reset.

A DCF record contains:

- A start record. Placed at UTEST_OFFSET, it indicates to the chip that the specified data records must be processed. See Table 226 that shows a general format of the start record.
- Application-specific number of data records. These follow the start record, as required.
- A stop record. Its presence indicates that the processing must stop. See Table 228 for a general format of the stop record. Only the STOP field needs to be 1 to form a stop record—all other fields are ignored. Also, an unprogrammed location in Utest flash memory is interpreted as a stop record.

Table 226. DCF start record

05AA 55AFh
0000 0000h

Table 227. DCF stop record

Reserved	1
Reserved	

A data record is structured in a way similar to a CPU-write instruction—comprising a 15-bit client select field, a 15-bit address field, and a 32-bit payload data field plus a STOP field. See Table 228 for details.

In a data record, the value of the STOP field must always be 0. Some clients support a parity (PRTY) field too.

Table 228. Format of a DCF data record

WDATA[31:0]			
CS[14:0]	ADDR[16:2]	PRTY	STOP

If *n* data records are to be stored in Utest, the data structure must be as shown in the next table.

Table 229. Series of DCF records in Utest

Address offset	Data			
00h	05AA 55AFh			
04h	0000 0000h			STOP = 0
08h	WDATA[31:0]			
0Ch	CS[14:0]	ADDR[16:2]	PRTY	STOP = 0
10h	WDATA[31:0]			
14h	CS[14:0]	ADDR[16:2]	PRTY	STOP = 0
8n - 1 + 0h	Reserved			
8n - 1 + 4h	Reserved			1
8n + 0h				
8n + 4h				

An unprogrammed record must not exist in the data structure because that is interpreted as a stop record. This leads to the subsequent records being ignored. In this case:

- You need to program the records in several sessions, each time appending new records at the end of the list, as shown in the next figure.
- A record may overwrite a client's value defined by a previous record. However, not all clients allow overwrites— that depends on their individual implementation.

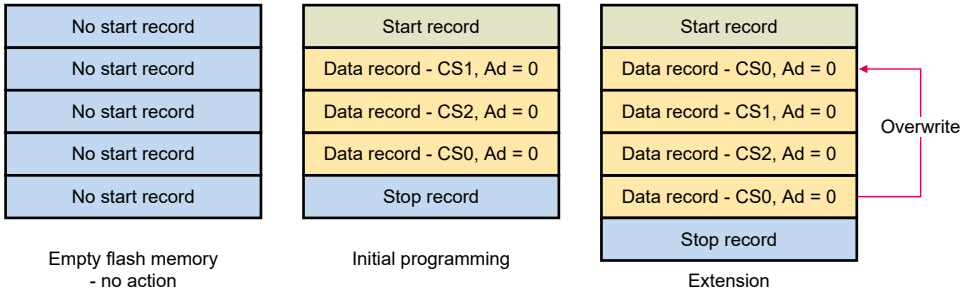

Figure 161. Appending DCF records

Some of the DCF records require parity bits, and the parity scheme used is even parity. So, the number of 1s in the WDATA and PRTY fields needs to be even. For example, if the WDATA field has the value 0000_0001h, the value of the PRTY field needs to be 1 so that the total number of 1s is even.

NOTE

You must ensure that DCF records are programmed uninterruptedly and the process completes without an error.

39.2.3 DCF error recording

DCF errors are recorded in DCM for both types of clients—spread spectrum safe and normal. See DCF client error mechanism for details on spread spectrum safe clients.

39.2.4 DCF client error mechanism

The DCM consists of DCMMISC[DCMCERS] for detecting faulty DCF records. The DCMSRRn registers capture the details up to 16 faulty records. The DCMCERS bit can be cleared by writing 1 to it.

While scanning the flash, in case if a faulty record is encountered, the DCMMISC[DCMCERS] gets set indicating that there is atleast one faulty record. In such a case, the user can identify the details about the faulty record in the DCMSRRn registers and should update the flash memory with a new record, provided the record is not write-once.

For example, in the image below, if the faulty DCF record is DCF2, then the correct DCF record must also be DCF2. Even in case if the faulty record is updated, the DCM stores the faulty record via the DCMMISC[DCMCERS] and DCMSRRn registers.

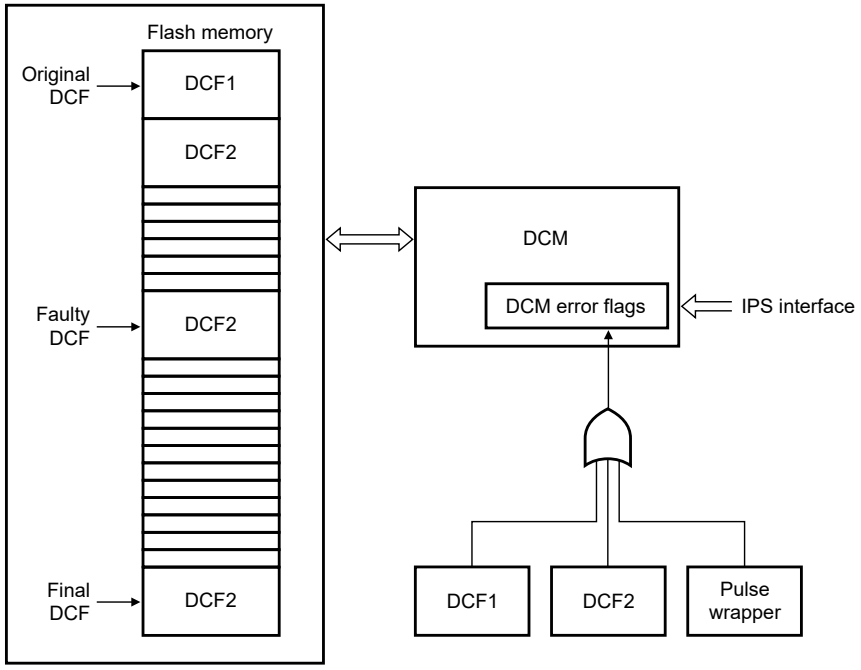

Figure 162. DCF error and CERS handling

39.2.5 DCF error detection mechanism

This figure shows that a faulty DCF record is loaded between the original and final DCF record sets.

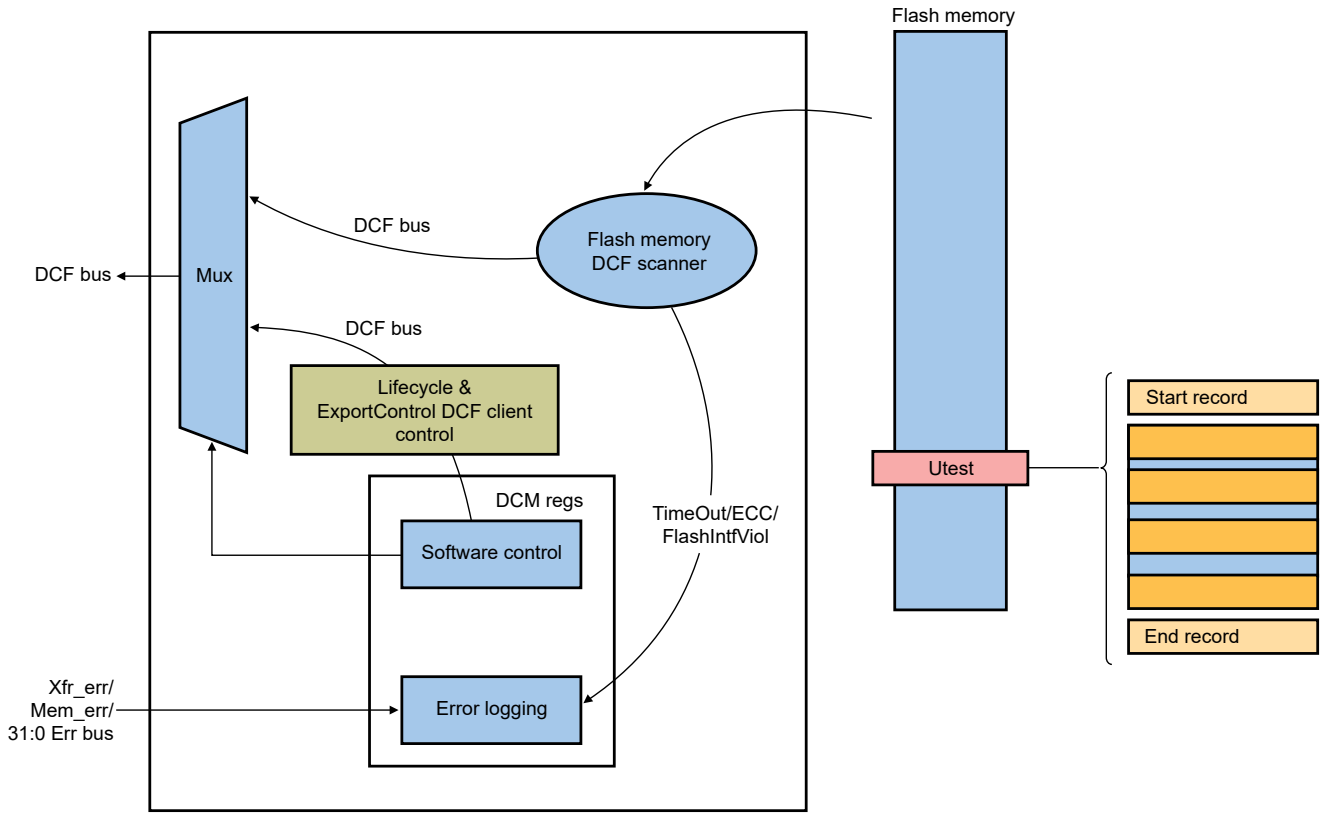

Figure 163. DCF error detection mechanism

39.2.6 LC

DCM determines the LC of the chip by reading the LC slots from the Utest flash memory. This read operation is performed during the reset phase, with normal timings. The operating monitors and an ECC check protect the operation. Additionally, a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC contains one of the following values:

- OEM production (OEM_PROD)
- In field (IN_FIELD)
- Pre-FA
- FA

The DCM LC progresses in the direction shown in this figure:

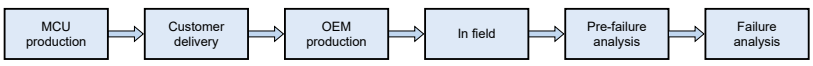

Figure 164. LC sequence

The LC is written into six slots, 128 bits each, and at fixed locations in the Utest flash memory blockblock. Each LC slot is read in a single atomic operation and is organized in two types of fields:

- Valid
- Invalid

Depending on the possible combinations of data programmed into these fields, each LC slot indicates one of the four possible statuses as shown in Table 230. To know more about LC slots, see Table 231.

Table 230. LC slot status

LC slots		LC slot value
Valid field (64 bits)	Invalid field (64 bits)	
Erased	Erased	Erased
Marked	Erased	Active
Marked	Marked	Inactive
Other values		Illegal

In this case, "Marked" refers to a value that is configured based on the bit pattern 55AA_50AF_55AA_50AFh, and "Erased" is detected using the bit pattern FFFF_FFFF_FFFF_FFFFh.

Table 231. LC slots

LC slot 2 OEM_PROD	LC slot 3 IN_FIELD	LC slot 4 Pre-FA	LC slot 5 FA	Resulting LC
Active	Erased	Erased	Erased	OEM_PROD
Inactive	Active	Erased	Erased	IN_FIELD
Inactive	Inactive	Active	Erased	PFA
Inactive	Inactive	Inactive	Active	FA
Erased	Erased	Erased	Erased	System reset
Illegal	Illegal	Erased	Erased	IN_FIELD

NOTE

When triggering DCM for rescanning the software, you must ensure that the flash memory program and erase fields are not set. Otherwise, DCM does not configure the chip and ignores all data returned from the flash memory. This results in LC becoming IN_FIELD. All DCF clients indicate their default values in this case.

39.3 DCM register descriptions

39.3.4 LC Scan Status (DCMLCS)

Offset

Register	Offset
DCMLCS	8h

Function

Stores the status of LC scanning. By default, the status of each LC is "not yet scanned."

This register:

- Resets on destructive reset.
- Always returns 0 in a valid IN_FIELD LC (in LC without an error).

This register captures the errors related to LC scanning on each of these resets: POR, destructive, and functional. If an error is captured, its status in this register is cleared by writing 1 to the corresponding field or to any of the destructive or POR events.

All LC slot errors are captured and cleared independently.

Chapter 40
Messaging Unit (MU)

40.1 Chip-specific MU information

40.1.1 MU instances and configuration

This chip includes MUs for communication across the different cores. Each MU includes two interfaces, MUA and MUB. Two different processors control them for communication.

Table 232 indicates the MUs and their interfaces present in different parts of the S32K3 chip family. The table also summarizes the implementation of this module in each chip of the S32K3 product series.

NOTE

The HSE_B core controls the MUA interface of MU_0 and MU_1. Therefore, the application core cannot control the interface.

Table 232. MU instances

Instance	S32K388, S32K389	S32K328, S32K338, S32K358	S32K348	S32K344	S32K324	S32K314	S32K342, S32K341	S32K322	S32K312	S32K311, S32K310	Use case
MU_0	Yes										Communication between HSE_B and application cores
MU_1	Yes										
MU_2	Yes		No		Yes	No		Yes	No		Communication between application cores
MU_3	Yes	No									
MU_4	Yes	No									

The base address of MU_1's MUB interface is different across the S32K3xx product series because AIPS_2 is unavailable in S32K312 and S32K311. Table 233 summarizes this difference.

Table 233. Base-address difference in MU_1's MUB interface across S32K3xx product series

	S32K388, S32K389, S32K328, S32K338, S32K348, S32K358, S32K344, S32K324, S32K314, S32K342, S32K341, S32K322	S32K312, S32K311, S32K310
Base address	404E_C000h	4039_0000h

NOTE

- For S32K344/S32K324/S32K314/S32K312/S32K311/S32K310 reset value of MUA_VER and MUB_VER register is 0300_000Fh.
- For others, reset value of MUA_VER and MUB_VER register is 0309_000Fh.

40.2 Overview

MU enables two processors on a chip to communicate and coordinate by passing messages (for example, data, status, and control) through the MU interface. MU also allows one processor to signal the other processor using interrupts.

MU must synchronize the accesses from one side to the other because MU can manage messaging between processors using different clocks. MU accomplishes synchronization using two sets of matching registers: processor A-facing and processor B-facing.

40.2.1 Block diagram

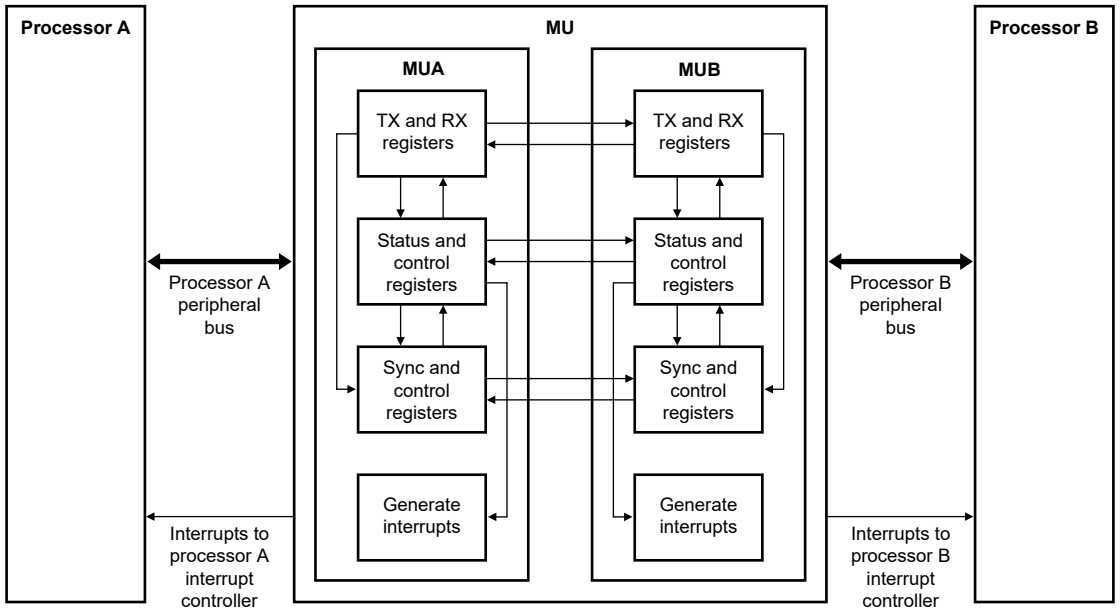

Figure 165. Block diagram

40.2.2 Features

- Memory-mapped registers (MU is connected as a peripheral under the peripheral bus on the processor A-side and processor B-side)
- Synchronized message transfers between cores

  - To send data or messages from one side to the other, MUA provides 4 transmit registers and 4 receive registers. MUB provides 4 transmit registers and 4 receive registers.
  - Transmit empty flags (TSR[TEn]) and receive full flags (RSR[RFn]) facilitate the transfer of data or messages between cores on both sides of MU.
  - A synchronization mechanism updates the transmit and the receive flags. There is an inherent latency between updating the flag on one side and reflecting its status on the other side. See Event update timing.
  - MU has a 3-bit flag data register, which you can use to send flag data between the two MU sides.
- Interprocessor interrupts
  - MU has 9 interrupt sources on each side (processor A-side, processor B-side) for signaling the other processor. You can use the interrupts for notification of receive and transmit events and for general-purpose signaling between processors. There are 1 general-purpose interrupt requests available and 8 receive and transmit interrupt sources.
- Reset (Each processor can issue a reset to MU via CR[MUR], which is a self-clearing field).

40.3 Functional description

MU enables two cores (processor A and processor B) to communicate with each other:

- By sharing messages and data.
- By enabling one core to wake the other core by using interrupts.

The messaging, control, and status registers of the two cores are mapped to processor A memory and processor B memory as a regular peripheral. The peripheral data bus is 32 bits wide inside MU.

Messaging logic is used with shared memory. Various messaging methods can implement a messaging protocol. For example, a message could mean one of the following:

- A message of *n* words has been written starting at offset *x* in the memory.
- The previous data block that was sent has been read.

The ability to keep messaging logic independent of the shared memory is not restricted to a predefined hardware protocol. The software required to manage the messaging is short and straightforward.

Most of the messaging mechanisms are symmetric. They are duplicated and are available on both the processor A side and processor B side. The messaging mechanisms are:

- 4 32-bit transmit registers, which are each reflected in 4 read-only receive registers on the side of the other processor. These registers can transfer 32-bit word messages or the frame information of the messages written to the shared memory. For example, they can transfer the number of words, initial address, and message type code.
- Writing to a transmitter-side transmit register (TR*n*) clears the Transmitter Empty flag in the transmitter-side Status register (TS*n*[TE*n*]), and sets the Receiver Full flag in the receiver-side Status register (RS*n*[RF*n*]). Setting the flag on the receiver side can trigger an interrupt on the receiver side (a maskable receive interrupt).
- Reading a receiver-side receive register (RR*n*) clears the Receiver Full flag in the receiver-side Status register (RS*n*[RF*n*]), and sets the Transmitter Empty flag in the transmitter-side Status register (TS*n*[TE*n*]). Setting the Transmitter Empty flag can trigger an interrupt on the transmitter side (a maskable transmit interrupt).
- 1 general-purpose interrupt request flags are reflected in General-purpose Status (GSR) on the receiver side.
- 3-bit flag data is transmitted from Flag Control (FCR) to Flag Status (FSR) on the side receiving the flag data. SR[FUP] sets when the flag data is transmitted and clears when the receiving side acknowledges the flag data (the flag is updated).

Writing to a transmit register signals to the receiver side that data is ready for retrieval.

Do not write to the transmit register again without verifying that the data is retrieved. The transmitter side cannot determine the exact time that the receiver attempts to retrieve the data. Before attempting to write to the transmit register again, the transmitter side must wait for the Transmitter Empty interrupt or it must poll TSR[TE*n*].

Reading a receive register signals to the transmitter side that data can be written to that register.

Do not read the receive register again without verifying that the data is written. The receiver side cannot determine the exact time that the transmitter attempts to write the data. Before attempting to read the receive register again, the receiver side must wait for the Receiver Full interrupt or it must poll RSR[RF*n*].

40.3.1 Submodules

40.3.1.1 MUA side

MUA receives its register configuration via the processor A peripheral bus. It sends or receives messages to or from MUB. Processor A can receive messages by reading MUA registers, and MUA can send interrupts to processor A when interrupts are enabled.

NOTE

Processor B is not allowed to access MUA register. Processor C, if exist, is also not allowed to access MUA register.

TRDC might be needed to prevent such illegal access.

40.3.1.2 MUB side

MUB receives its register configuration via the processor B peripheral bus. It sends or receives messages to or from MUA. Processor B can receive messages by reading MUB registers, and MUB can send interrupts to processor B when interrupts are enabled.

NOTE

Processor A is not allowed to access MUB register. Processor C, if exist, is also not allowed to access MUB register.

TRDC might be needed to prevent such illegal access.

40.3.2 Event update timing

The messaging side of each processor has a hardware mechanism to send event update requests to the other processor. An event occurs when the status register of the receiving processor must reflect any information change. The event update latency is the delay between the event being ready at one processor and the resulting update at the status register of the other processor:

- The minimum event latency is (1 clock cycle of the sending side) + (2.5 clock cycles of the receiving side). This minimum case happens when no event is pending when the new event occurs.
- The maximum event latency is (6 clock cycles of the sending side) + (6.5 clock cycles of the receiving side). The maximum case happens when the event occurs just after a previous event is sent to the other side.

The event update latency varies depending on the time at which the subsequent event is triggered.

40.3.3 Clocking

Table 234. MU clocks

Clock name	Description
Bus clock MUA	Used only for bus accesses to MUA control and configuration registers
Bus clock MUB	Used only for bus accesses to MUB control and configuration registers

40.3.4 Resets

The following sections list the reset sources included in MU. Each reset performs a different function for the MU module compared to the function it performs for the system.

40.3.4.1 Asynchronous system reset

When the asynchronous system reset on either side of MU is asserted, SR[MURS] becomes 1 until the asynchronous system reset sequence on both the MUA and MUB sides ends. Verify that SR[MURS] becomes 0 before accessing MU.

The asynchronous system reset on one side of MU resets the other side of MU. The reset forces all control and status registers to return to their default values and clears all internal states. The following table shows the exceptions to this behavior.

Table 235. Exceptions to asynchronous system reset

MUA-side exceptions	MUB-side exceptions
MUB_CR[MURIE]	MUA_CR[MURIE]
MUB_SR[MURIP]	MUA_SR[MURIP]
MUB_SR[MURS]	MUA_SR[MURS]

40.3.4.2 MU software reset

Writing 1 to CR[MUR] causes most control and status registers to return to their default values and clears all internal states.

The instruction immediately following the assertion of CR[MUR] must not write to the MU registers. The reset sequence may overwrite such a write, with the register retaining the reset value. To know the end of the reset sequence for both processors, monitor the value of SR[MURS]. After the reset sequence on both processors has ended, a write to the MU registers can be attempted.

NOTE

The process of CR[MUR] becoming 1 is delicate because it asynchronously affects the registers on the other side. CR[MUR] becoming 1 may cause unpredictable behavior if, for example, the other processor is concurrently testing an MU register field (TSR[TE*n*] in the other processor). Before writing 1 to CR[MUR], verify that the other processor is not engaged in an MU signaling activity.

40.3.5 Interrupts

MU controls interrupt requests that one processor makes to the other processor. This section describes all the interrupts that the module generates.

MU can generate these interrupt sources individually to send to the processors:

- 4 receive interrupts (asserted when the Receive Full flags are set in Receive Status (RSR) and enabled in Receive Control (RCR)) for each receive register
- 4 transmit interrupts (asserted when the Transmit Empty flags are set in Transmit Status (TSR) and enabled in Transmit Control (TCR)) for each transmit register
- 1 general-purpose interrupt (asserted when the GIP flag is set in General-Purpose Interrupt Enable (GIER) and enabled in General-Purpose Interrupt Enable (GIER))

All interrupts are maskable in the processor control registers: TCR, RCR, GIER, and CR. MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, receive 0 and receive 1, or any transmit or general-purpose interrupt) can be asserted simultaneously. The interrupt controller must resolve the priority of these interrupts at the chip level.

Triggering any enabled interrupt wakes the processor from below mode before servicing the interrupt

The software (as part of the interrupt handler) must clear the general-purpose interrupt pending flag (GSR[GIP0]) to deassert the request to the interrupt controller.

When a processor writes to the general-purpose interrupt flag (GCR[GIR0]), MU synchronizes the write event to the other processor to set the general-interrupt request pending flag (GSR[GIP0]). When GSR[GIP0] is set, if the general-purpose interrupt is enabled on the receiving processor side (GIER[GIE0] is 1), the transmitting-side general-purpose interrupt is issued to the receiving processor, which clears this interrupt by writing 1 to GSR[GIP0]. The interrupt is deasserted as soon as the write to

GSR[GIP0] occurs. MU synchronizes the write event of GSR[GIP0] to the other processor. The synchronized signal clears the GIR0 flag.

Before writing 1 to GCR[GIR0], verify that this field is 0, which means that a general interrupt is not pending. Generally, MU ignores writing 1 to this field while the field is already 1, but in some cases it may issue a second interrupt.

40.4 External signals

This module has no external signals.

40.5 Initialization

MU does not require initialization.

40.6 Application information

MU facilitates messages between processors. For example, MU passes:

- Short messages. Transmit registers can pass short messages from 1 to 4 words in length for processor A and from 1 to 4 words for processor B. For example, for a four-word message, only one register must have its corresponding interrupt enabled on the receiving side. The first three words of the message are written to the registers with masked interrupts. The fourth word is written to the last register, triggering an interrupt on the receiving side.
- Frame information. Transmit registers can pass frame information for long messages written to the shared system memory. Such frame information normally includes a start address and a number of words. It can include a message type code.
- Event notices and requests. MU can signal events and requests that do not include data words between processors using general-purpose interrupts. For example, one such event is acknowledging that a long message is read from the shared system memory.
- Fixed-length data. Formatted data with a fixed length can be written to predetermined locations in the shared memory. A processor can use general-purpose interrupts to signal to the other processor that the data is ready.
- Announcements. A processor can use the 3 flags to announce its current program state or other billboard messages to the other processor.

40.6.1 Messaging protocols using interrupts

The example below describes a four-word messaging sequence sent between the processor A and processor B.

The transmitting processor writes to the transmit registers sequentially. When $n = 0$, 1, and 2, the interrupts are disabled, so no interrupt goes to the processor (although interrupt conditions occur). For $n = 3$, the interrupt is enabled, and MU generates the last receive interrupt request.

1. Write sequence:
    a. The transmitting processor writes the message information sequentially to its Transmit registers 0, 1, 2.
    b. When the write to Transmit register 3 occurs, RSR[RF3] is set after synchronization. It immediately triggers the receive full 3 interrupt on the receiving processor.
2. Read sequence:
    a. The receiving processor receives the receive full 3 interrupt and starts reading the message transferred from the receive registers.
    b. After the receiving processor reads Receive register 3, MU clears RSR[RF3].

Table 236 and Figure 166 describe the messaging model, using transmit and receive registers and the interrupt messaging protocol.

Table 236. Interrupt messaging protocol (generalized)

Step	Action	Description
1	Processor A writes data.	RR*n* on processor B's side reflects a data write to TR*n* by processor A.
2	Clear the transmitter empty flag and set the receiver full flag.	The data write to TR*n*: • Clears TSR[TE*n*] on the processor A side. • Sets RSR[RF*n*] on the processor B side.
3	Generate the receive interrupt request.	Setting RSR[RF*n*] generates a receive interrupt request to processor B.
4	Processor B reads the data.	After receiving the receive interrupt request, processor B performs a data read of RR*n*.
5	Clear the receiver full flag and set the transmitter empty flag.	Reading the data from the RR*n* register: • Clears RSR[RF*n*] on the processor B side. • Sets TSR[TE*n*] on the processor A side.
6	Generate the transmit interrupt request.	Setting TSR[TE*n*] generates a transmit interrupt request to processor A.

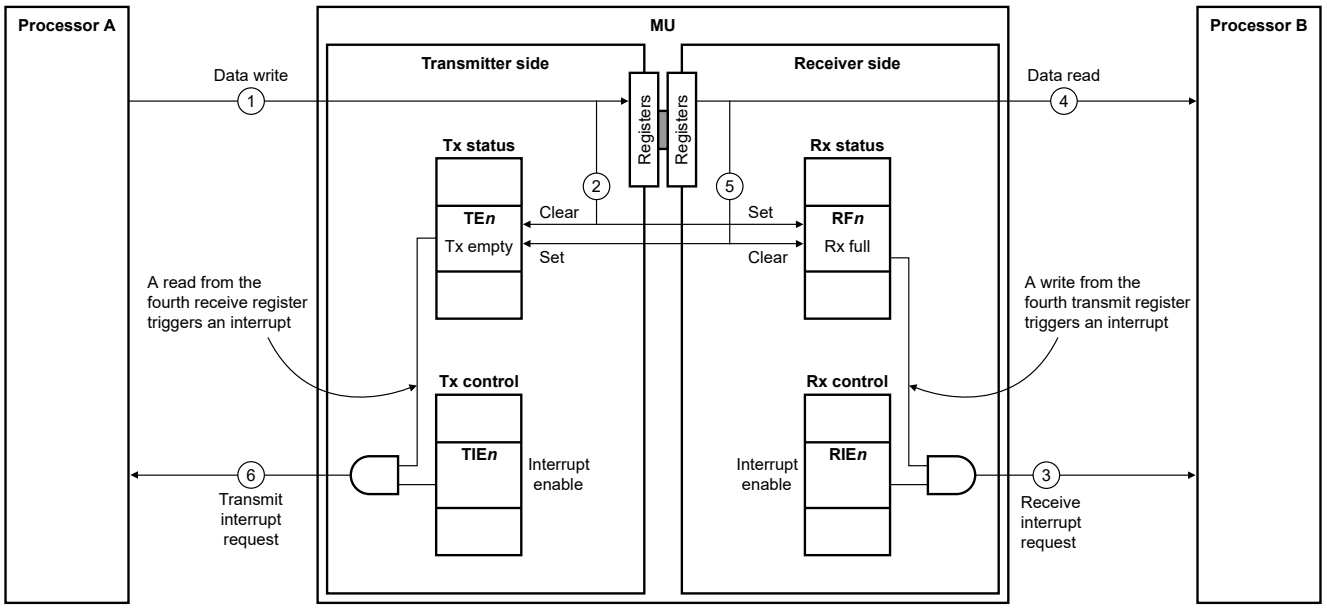

Figure 166. Messaging model using transmit and receive registers

You can use the messaging hardware to implement messaging protocols for an array of message types. MU provides full support for interrupt and polling management schemes.

40.6.2 Messaging protocols using event interrupts

MU can signal events and requests that do not include data words between processors using general-purpose interrupts.

Formatted data with a fixed length can be written to predetermined locations in the shared memory. A processor can use a general-purpose interrupt to signal to the other processor that the data is ready.

A processor can use the 3 flags to announce its current program state (or similar messages) to the other processor.

Table 237 and Figure 167 describe the event steps when the processor triggers a general-purpose interrupt.

Table 237. General-purpose interrupt messaging protocol (generalized)

Step	Action	Description
1	Processor A sets its associated general-purpose interrupt request flag.	Processor A sets GCR[GIR0].
2	The general-purpose interrupt request pending status flag is set.	GSR[GIP0] is set.
3	MU generates the general-purpose interrupt request to processor B.	Setting GSR[GIP0] generates the general-purpose interrupt request to processor B. GIER[GIE0] must be set for processor B.
4	Processor B reads the status register.	Processor B reads GSR[GIP0].
5	Processor B services the interrupt.	—
6	Processor B sets GSR[GIP0] to clear the interrupt.	Processor B writes 1 to the corresponding GSR[GIP0] flag to clear the interrupt.
7	GCR[GIR0] is cleared.	Setting GSR[GIP0] clears GCR[GIR0] on the processor A side.

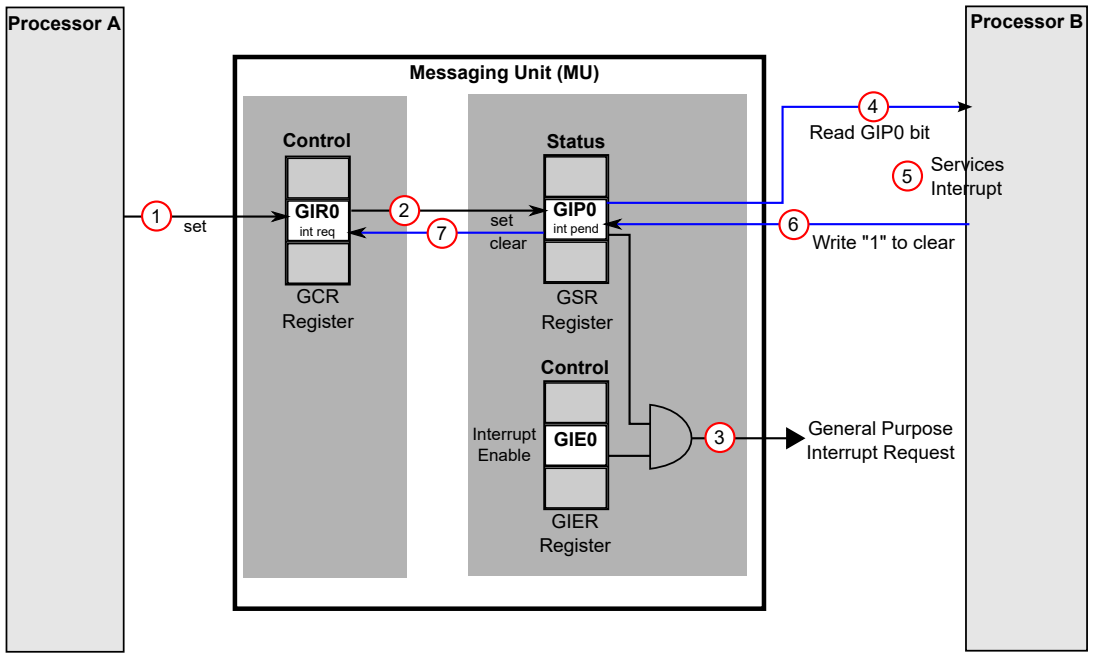

Figure 167. Messaging model using a general-purpose interrupt

40.6.3 Exclusive access to shared memory

MU can signal one processor about its current access to shared memory. This signaling prevents the other processor from overwriting data during the exclusive memory access period.

The following tables describe the signaling protocol that processor A uses to inform processor B about its current access (write) to shared memory:

- Table 238 shows processor A performing an exclusive access to shared memory.
- Table 239 shows processor B scanning for transaction information.
- Table 240 shows processor B accepting exclusive access from processor A.
- Table 241 shows processor B rejecting exclusive access from processor A.

According to the examples shown in the following tables, GCR[GIR0], RR*n*, and TR*n* are reserved to support exclusive access to the shared memory protocol.

Table 238. Processor A performs an exclusive access to shared memory

Step	Action	Description
1	Processor A sends the GIR0 request to processor B using the processor A control register.	Before processor A performs an exclusive access to the shared memory, it sends a GIR0 request to processor B.
2	Processor A sends an exclusive-access request using a transmit data register (TR*n*).	Processor A sends an exclusive-access request (command, location, and length of target access) to processor B using a selected transmit data register (TR0).
3	Processor A waits for a dedicated interrupt from processor B.	Processor A waits for a dedicated interrupt (as an acknowledgment) triggered by processor B before proceeding.
4	Processor A accesses the shared memory.	After receiving a dedicated interrupt from processor B, processor A proceeds.

Table 239. Processor B scans for transaction information

Step	Action	Description
1	Processor B receives an interrupt from a receive data register (RR*n*).	—
2	Processor B reads the receive data register (RR*n*).	—
3	Processor B scans the receive data register contents.	Processor B scans for transaction information (whether processor A has requested exclusive access).

Table 240. Processor B accepts exclusive access from processor A

Step	Action	Description
1	Processor B triggers a dedicated interrupt.	Processor B acknowledges the request from processor A by triggering a dedicated interrupt (ack) to processor A.
2	Processor B sends a code message to processor A.	With the acknowledge interrupt, processor B sends a code message to processor A through the selected transmit register (TR*n*). The message informs processor A that it can exclusively access the shared memory.

Table 241. Processor B rejects exclusive access from processor A

Step	Action	Description
1	Processor B ignores the request from processor A for exclusive access.	If processor B does not provide permission to processor A, processor B ignores the exclusive-access request.

40.6.4 Packet data transfers

The following table describes an example packet transfer sequence between processor B and processor A subsystems.

Table 242. Packet data transfer sequence

Step	Action	Description
1	Processor B requests DMA.	Processor B sends a DMA request to initiate the packet data transfer.
2	DMA data transfer	DMA acknowledges.
3		DMA starts transferring data from the specified processor B memory location to the specified shared memory.
4		DMA interrupts processor B to signal that the packet transfer has finished.
5	Processor B informs processor A that data is in shared memory.	Using a B-side transmit register, processor B sends a packet information message to processor A about the arrival of new packet data stored in shared memory. The message contains the command, location, and length of packet data.
6	Processor A receives an interrupt.	Processor A receives an interrupt (assuming its corresponding processor A MU-side receive interrupt is enabled). The pending processing task becomes active and processes packet data from memory.
7	Processor A reads data, then writes data.	Processor A reads or processes packet data from shared memory.
8		Processor A writes the result from packet processing to a separate buffer.
9	Processor A informs processor B that the transfer is finished.	After the processing of the packet data finishes, processor A informs processor B (using MU processor A-side transmit register, MUA_TR*n*).
10	Processor A sends an interrupt to processor B (a request for more data).	Processor B receives the next interrupt from processor A, in which processor A requests more packet data.

40.6.5 Freeing a processor from deadlock

During normal operation, one processor may determine that the other processor is not working or is deadlocked. Using Status (SR), the processor can use the methods in the following table to identify and correct the problem.

Table 243. Freeing a processor from deadlock

Processor mode	Technique	Description
—	Processor issues an interrupt.	The other processor can interrupt the processor by issuing one of the 9 (general purpose, receive, or transmit) interrupts.

40.7 Register definition

MU provides transmit and receive data registers (*x*TR0–*n*, *x*RR0–*n*) for communication between processor A and processor B. It also provides control registers (*x*CR) for operations such as interrupts and resets, and status registers (*x*SR) for checking the status of the other MU-side. Figure 168 shows the schematic for MU registers.

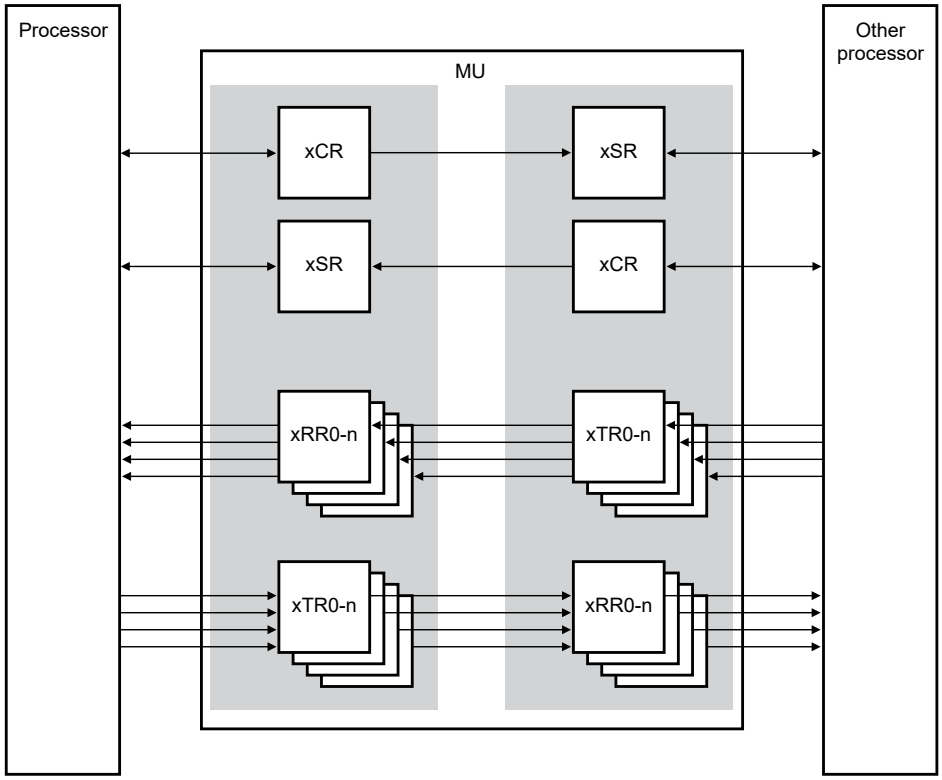

Figure 168. MU registers

40.7.1 MU register descriptions

This section contains the detailed register descriptions for MUA registers.

NOTE

A module transfer error to processor A or processor B is generated when:

- A read or write access is made to an invalid location.
- A write operation is performed on a read-only register on the processor A side or processor B side of MU.

23-16 GIR_NUM	General-Purpose Interrupt Request Number Specifies the number of general-purpose interrupt requests available (1).
15-8 RR_NUM	Receive Register Number Specifies the number of receive registers (4).
7-0 TR_NUM	Transmit Register Number Specifies the number of transmit registers (4).

40.7.1.4 Control (CR)

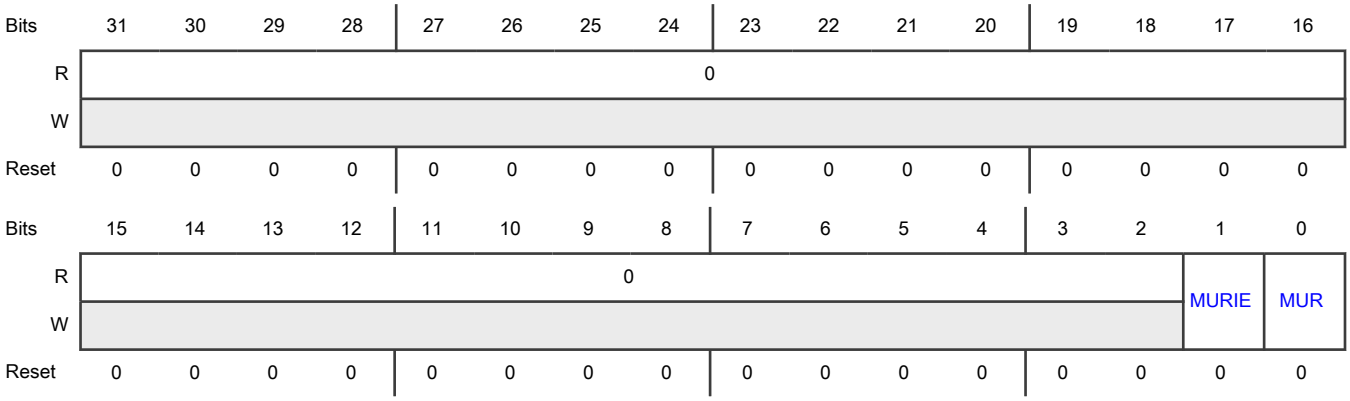
Offset

Register	Offset
CR	8h

Function

Controls MU reset and reset interrupt enable.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 MURIE	MUA Reset Interrupt Enable Enables the processor A-side MU reset interrupt request due to MU reset issued by MUB. If the value of this field is 1, an MU reset interrupt request is issued to processor A when MUA_SR[MURIP] = 1. If the value of this field is 0, MU ignores the value of MURIP and issues no MU reset interrupt request. Only a system reset can reset this field. CR[MUR] cannot reset this field. 0b - Disable 1b - Enable
0 MUR	MU Reset Resets MU. Writing 1 to this field resets the MUA and MUB sides. All internal states are cleared. It forces all control and status registers to return to their default values (except MURIE in MUA/B_CR registers; MURIP and MURS in MUA/B_SR registers). Before writing 1 to this field, interrupt processor B because writing 1 to this field may affect the ongoing processor B program. After writing 1 to this field, monitor the value of MUA_SR[MURS] to know when the reset sequence on the processor B-side has ended. This field always reads 0, and it becomes 0 during the MU reset sequence. 0b - Idle 1b - Reset

40.7.1.5 Status (SR)

Offset

Register	Offset
SR	Ch

Function

Shows the status of MU resets and the status of pending events and requests.

Fields

Field	Function
31-8 —	Reserved
7 —	Reserved
6 RFP	MUA Receive Full Pending Indicates whether a receive full message is pending. This field becomes 1 when MUB writes to a TR*n* register to send data to MUA. After this field becomes 1, MU checks RSR[RF*n*] to determine whether the data in the Receive register is ready for MUA to read it. This field becomes 0 when all MUA RR*n* registers are read, or when MU is reset. 0b - Not pending; MUB is not writing to a Transmit register 1b - Pending; MUB is writing to a Transmit register
5 TEP	MUA Transmit Empty Pending Indicates whether a transmit empty message is pending.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 when any TCR[TIE*n*] field is 1 and MUB reads the corresponding Receive (RR*n*) register. After this field becomes 1, MU checks TSR[TE*n*] to determine whether the data in the Transmit (TR*n*) register is ready for MUA to write to it. This field becomes 0 when write operations to all MUA Transmit (TR*n*) registers where TCR[TIE*n*] = 1 (transfer interrupt enabled) are completed, or when MU is reset. 0b - Not pending; MUB is reading no Receive (RRn) register 1b - Pending; MUB is reading a Receive (RRn) register
4 GIRP	MUA General-Purpose Interrupt Pending Indicates that MUB has sent a general-purpose interrupt request. This field becomes 1 when the MUB side sends a general-purpose interrupt request to the MUA side. GSR[GIP0] identifies which general-purpose interrupt request is received. This field becomes 0 when MUA_GSR[GIP0] is cleared, or when MU is reset. 0b - No request sent 1b - Request sent
3 FUP	MUA Flag Update Pending Indicates whether a flag update request is pending. MU generates this request when there is a change to the F*n*[2:0] bits of MUA_FCR. This field becomes 1 when the MUA side sends a flag update request to the MUB side. This field becomes 0 when MU acknowledges this flag update request internally (the flag is updated) from the MUB side, or during MU reset. No flag update changes are allowed when this field is 1. When FUP = 1, a write to the F*n*[2:0] bits of MUA_FCR does not generate a flag update event. The F*n*[2:0] bits do not change. If SR[EP] = 1 (event pending), writing to MUA_FCR does not immediately cause this field to become 1. 0b - No pending update flags (initiated by MUA) 1b - Pending update flags (initiated by MUA)
2 EP	MUA Side Event Pending Indicates a pending side event when the MUA side sends an event update request to the MUB side. An event is any hardware message that the Status register on the MUB side reflects. For example, an event occurs when Transmit register 0 is the target of a write operation. During normal operations, the update mechanism for this field operates automatically. MU clears this field automatically when the event update acknowledgment is received, or when MU resets. To ensure that events are posted to MUB, verify that this field is 0. If it is 1, wait and continue to poll this field until it becomes 0. 0b - Not pending 1b - Pending
1	MU Reset Interrupt Pending Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
MURIP	Indicates whether processor B has issued an MU reset. This flag is set after processor B initiates an MU reset by setting MUB_CR[MUR]. If CR[MURIE] = 1, the processor A MU reset interrupt request is issued when processor B writes 1 to MUB_CR[MUR]. Clearing this flag also clears the MU reset interrupt request. Only a system reset can reset this flag. MU reset cannot reset this flag. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Reset not issued 1b - Reset issued When writing 0b - No effect 1b - Clear the flag
0 MURS	MUA and MUB Reset State Indicates the reset state of MUA and MUB. This field becomes 1 during any system reset or MU reset from the MUA or MUB side. This field becomes 0 when the reset sequence on both MUA and MUB sides ends. After issuing any of the aforementioned reset events, verify that this field is 0 before starting any access. 0b - Out of reset 1b - In reset

40.7.1.6 Flag Control (FCR)

Offset

Register	Offset
FCR	100h

Function
Configures MUB_FSR[F*n*] flags.

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0													F2	F1	F0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-3 —	Reserved
2-0 Fn	MUB to MUA-Side Flag Contains flags configured by the values written to MUB_FCR[F*n*], where *n* = 0 to 2. F*n* is the MUA-side flag configured by the values written to MUB_FCR[F*n*]. When MUB_FCR[F*n*] is written to, the write event updates MUA_FSR[F*n*], after the event update latency. 0b - MUB_FCR[Fn] = 0 1b - MUB_FCR[Fn] = 1

40.7.1.8 General-Purpose Interrupt Enable (GIER)

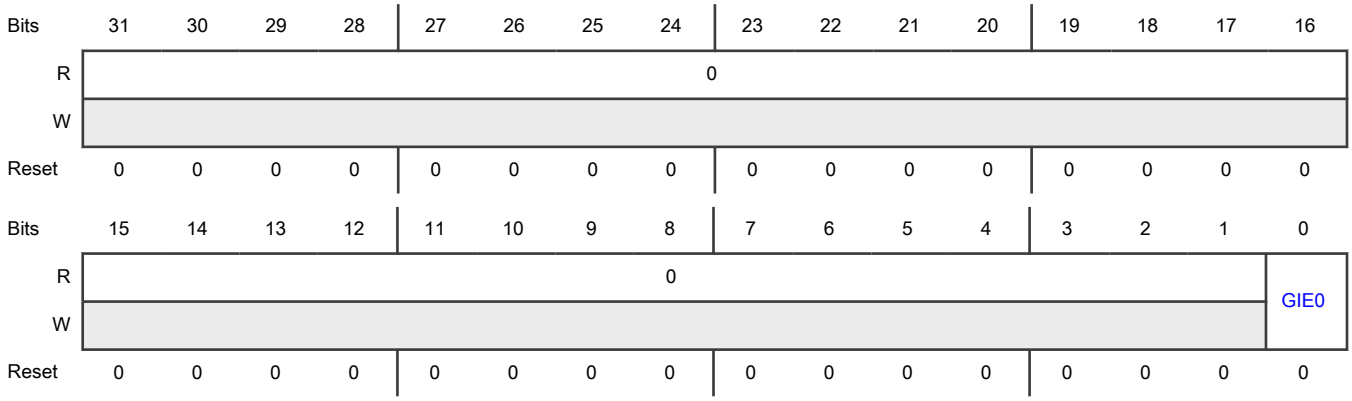
Offset

Register	Offset
GIER	110h

Function

Contains the MUA general-purpose interrupt enable fields.

Diagram



Fields

Field	Function
31-1 —	Reserved
0-0 GIEn	MUA General-purpose Interrupt Enable Enables general-purpose interrupt. There is one general-purpose interrupt (*n* = 0). When GIE0 = 1, a general-purpose interrupt *n* request is issued to processor A when MUA GSR[GIP0] = 1. If GIE0 = 0, the general-purpose interrupt request pending does not trigger the general-purpose interrupt. GIE0 becomes 0 when MU resets. 0b - Disable 1b - Enable

40.7.1.9 General-Purpose Control (GCR)

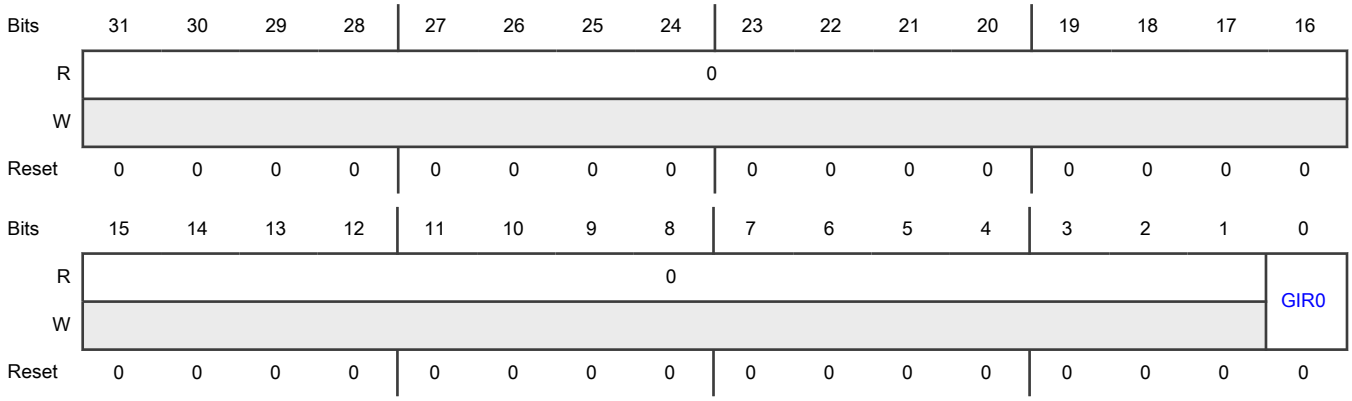
Offset

Register	Offset
GCR	114h

Function

Contains the MUA general-purpose interrupt request fields.

Diagram



Fields

Field	Function
31-1 —	Reserved
0-0 GIRn	MUA General-Purpose Interrupt Request Specifies whether general-purpose interrupts are requested to MUB. There is one general-purpose interrupt (*n* = 0). Writing 1 to GIR0 sets MUB_GSR[GIP0]. If MUB_GIER[GIE0] = 1, a general-purpose interrupt request is triggered on processor B. This field becomes 0 when MUB_GSR[GIP0] is cleared. This clearing informs MUA that the interrupt is accepted (cleared by software). To ensure proper operations, verify that GIR0 is 0 (no pending interrupt) before writing 1 to it. This field becomes 0 when MU resets. 0b - Not requested 1b - Requested

40.7.1.10 General-purpose Status (GSR)

Offset

Register	Offset
GSR	118h

Function

Contains the status of the MUA general-purpose interrupt pending requests.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0															GIP0
W																W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-1 —	Reserved
0-0 GIPn	MUA General-Purpose Interrupt Request Pending Indicates whether a general-purpose interrupt request is pending. There is one general-purpose interrupt (*n* = 0). GIP0 informs MUA that MUB_GCR[GIR0] changed from 0 to 1. If MUA_GIER[GIE0] = 1, a general-purpose interrupt request is issued to processor A. GIP0 is cleared when MU resets. After GIP0 is cleared, if MUA_GIER[GIE0] = 1, the general-purpose interrupt request is cleared on the MUA side. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not pending 1b - Pending When writing 0b - No effect 1b - Clear the flag

40.7.1.11 Transmit Control (TCR)

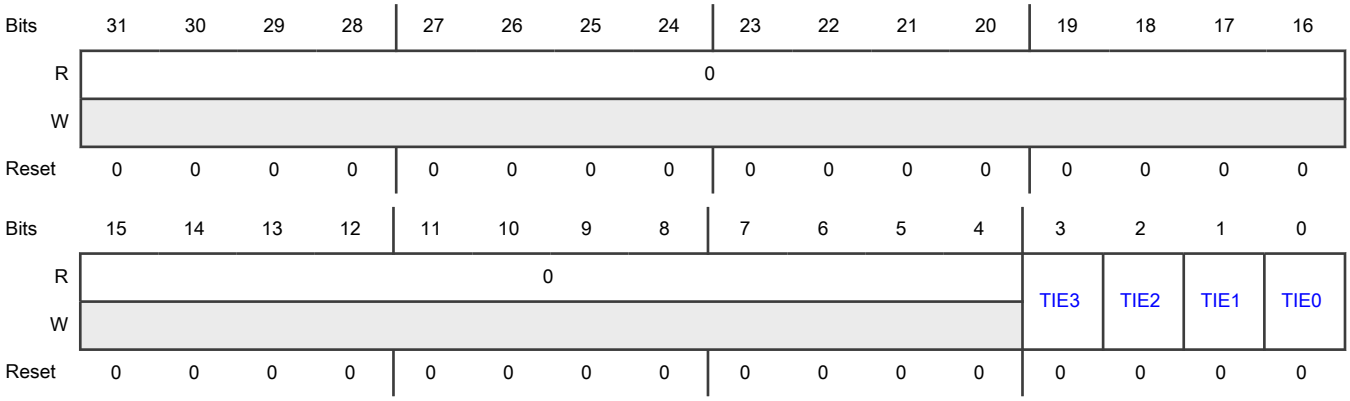
Offset

Register	Offset
TCR	120h

Function

Contains the MUA transmit interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TIEn	MUA Transmit Interrupt Enable Enables MUA transmit interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUA transmit interrupt *n* request is issued when MUA_TSR[TE*n*] is set. If this field is 0, MU ignores the value of MUA_TSR[TE*n*], and no MUA transmit interrupt *n* request is issued. 0b - Disable 1b - Enable

40.7.1.12 Transmit Status (TSR)

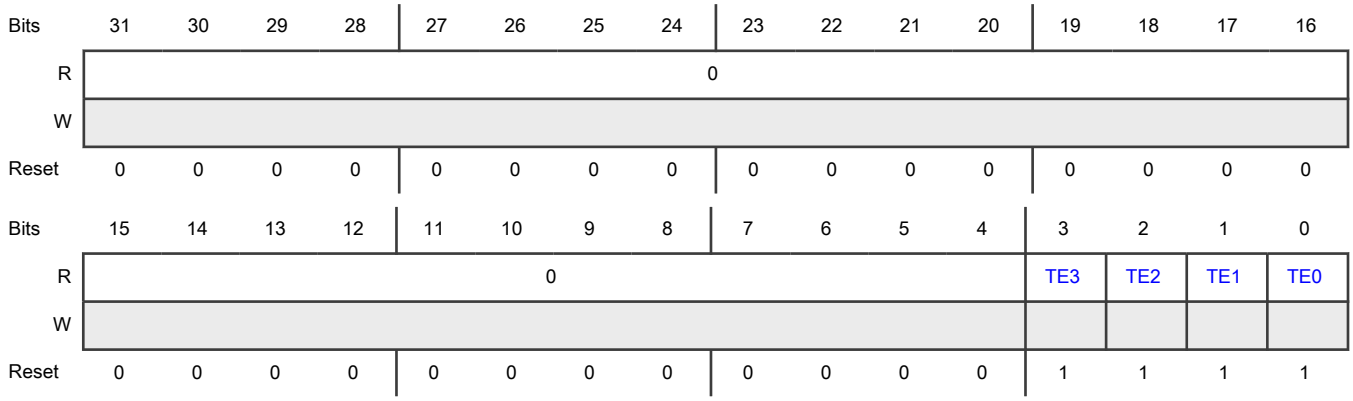
Offset

Register	Offset
TSR	124h

Function

Indicates whether the MUA transmit registers are empty.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TEn	MUA Transmit Empty Indicates whether MUA Transmit (TR*n*) register is empty, where *n* = 0 to 3. This field becomes 1 after the MUB_RR*n* register is read on the MUB side. When TE*n* = 1, it indicates to the MUA side that the MUA_TR*n* register is ready to be written on the MUA side. If MUA_TCR[TIE*n*] = 1, a transmit *n* interrupt is issued on the MUA side. This field becomes 0 after the MUA_TR*n* register is written to on the MUA side. After this field becomes 0, if MUA_TCR[TIE*n*] = 1, the transmit *n* interrupt request is cleared on the MUA side. This field becomes 1 when MU resets. 0b - Not empty 1b - Empty

40.7.1.13 Receive Control (RCR)

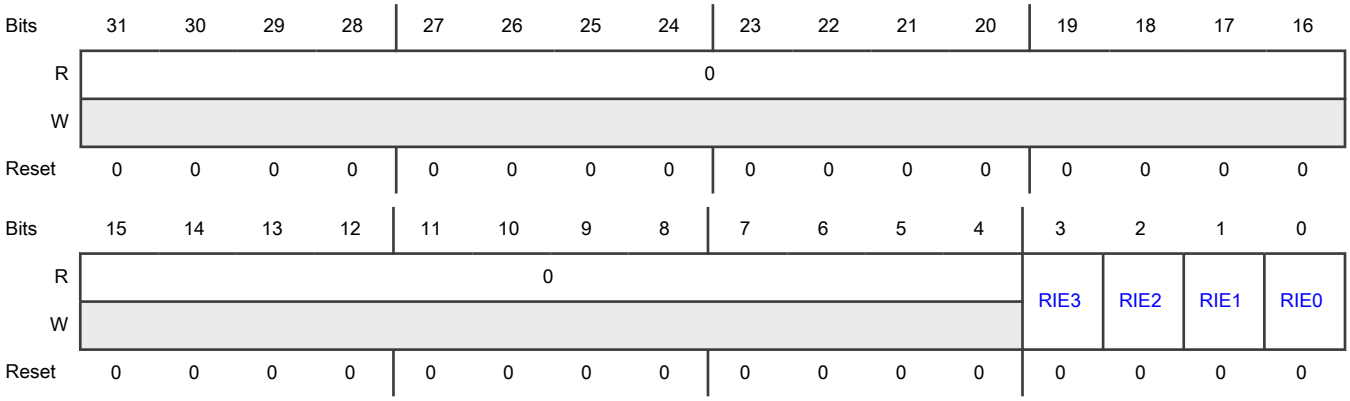
Offset

Register	Offset
RCR	128h

Function

Contains the MUA receive interrupt enables.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 RIEn	MUA Receive Interrupt Enable Enables MUA receive interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUA receive interrupt *n* request is issued when MUA_RSR[RF*n*] is set. If this field is 0, MU ignores the value of MUA_RSR[RF*n*], and no MUA receive interrupt request is issued. 0b - Disable 1b - Enable

40.7.1.14 Receive Status (RSR)

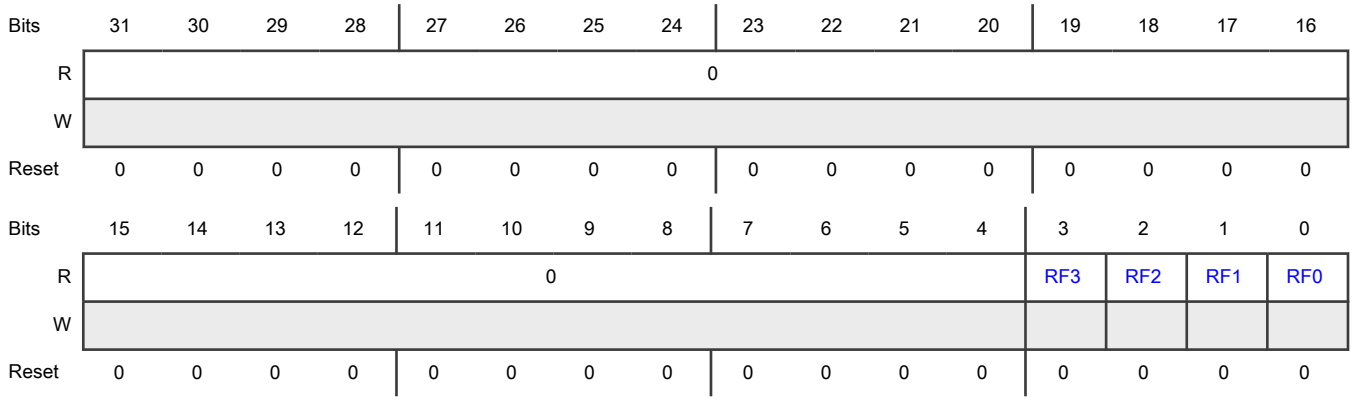
Offset

Register	Offset
RSR	12Ch

Function

Indicates whether the MUA receive registers are full.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 RFn	MUA Receive Register Full Indicates whether MUA Receive register (RR*n*) is full, where *n* = 0 to 3. This field becomes 1 when the MUB_TR*n* register is written to on the MUB side. When this field is 1, it indicates to the MUA side that new data in the MUA_RR*n* register is ready for MUA to read it. If MUA_RCR[RIE*n*] = 1, a receive *n* interrupt is issued on the MUA side. This field becomes 0 when the MUA_RR*n* register is read, or when MU is reset. After this field becomes 0, if MUA_RCR[RIE*n*] = 1, the receive *n* interrupt request is cleared on the MUA side. 0b - Not full 1b - Full

40.7.1.15 Transmit (TR0 - TR3)

Offset

Register	Offset
TR0	200h
TR1	204h
TR2	208h
TR3	20Ch

Function

Contains MUA transmit data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W	TR_DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0															
W	TR_DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TR_DATA	MUA Transmit Data Contains MUA transmit data. MUB_RR*n* reflects the data written to this register. The TR*n* and RR*n* registers are not double-buffered. Writing to MUA_TR*n* overrides the data readable in the MUA_RR*n* register. A write to the Transmit register clears MUA_TSR[TE*n*] on the transmitter side, and sets MUB_RSR[RF*n*] on the receiver side. You can write to this register only when MUA_TSR[TE*n*] = 1. Reading this register returns all zeroes.

40.7.1.16 Receive (RR0 - RR3)

Offset

Register	Offset
RR0	280h
RR1	284h
RR2	288h
RR3	28Ch

Function

Contains MUA receive data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RR_DATA															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RR_DATA															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 RR_DATA	MUA Receive Data Reflects the data written to MUB TR*n*. Reading this register clears MUA_RSR[RF*n*] on the receiver side, and sets MUB_TSR[TE*n*] on the transmitter side. You can read this register only when MUA_RSR[RF*n*] = 1. Reading it before MUA_RSR[RF*n*] becomes 1 may result in reading incorrect data. Poll MUA_RSR[RF*n*] to confirm it is set before reading RR*n*. Writing to this register generates an error response to MUA.

40.7.2 MU register descriptions

This section contains the detailed register descriptions for MUB registers.

NOTE

A module transfer error to processor A or processor B is generated when:

- A read or write access is made to an invalid location.
- A write operation is performed on a read-only register on the processor A side or processor B side of MU.

40.7.2.1 MU memory map

MU_0.MUB base address: 4038_C000h

MU_1.MUB base address: 404E_C000h

40.7.2.2 Version ID (VER)

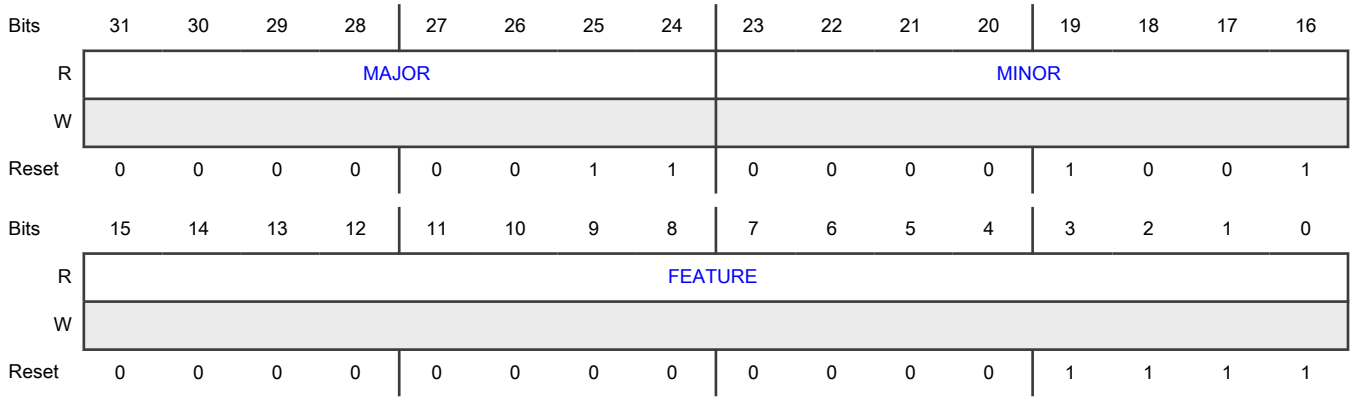
Offset

Register	Offset
VER	0h

Function

Determines the version ID and feature set number of MUB.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number
23-16 MINOR	Minor Version Number
15-0 FEATURE	Feature Set Number Indicates the feature set number. MU implements: • Standard features • Expanded number of TR*n*/RR*n* registers

40.7.2.3 Parameter (PAR)

Offset

Register	Offset
PAR	4h

Function

Defines the number of flags, transmit registers, receive registers, and general-purpose interrupt requests available for MU.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	RR_NUM								TR_NUM							
W																
Reset	See Register reset values.															

Register reset values

Register	Reset value
PAR	MU_0.MUB,MU_1.MUB: 2020_0404h MU_2.MUB–MU_4.MUB: 0301_0404h

Fields

Field	Function
31-24 FLAG_WIDTH	Flag Width Specifies the number of flag bits (32) in the Flag Control (FCR) and Flag Status (FSR) registers.
23-16 GIR_NUM	General-Purpose Interrupt Request Number Specifies the number of general-purpose interrupt requests available (32).
15-8 RR_NUM	Receive Register Number Specifies the number of receive registers (4).
7-0 TR_NUM	Transmit Register Number Specifies the number of transmit registers (4).

40.7.2.4 Control (CR)

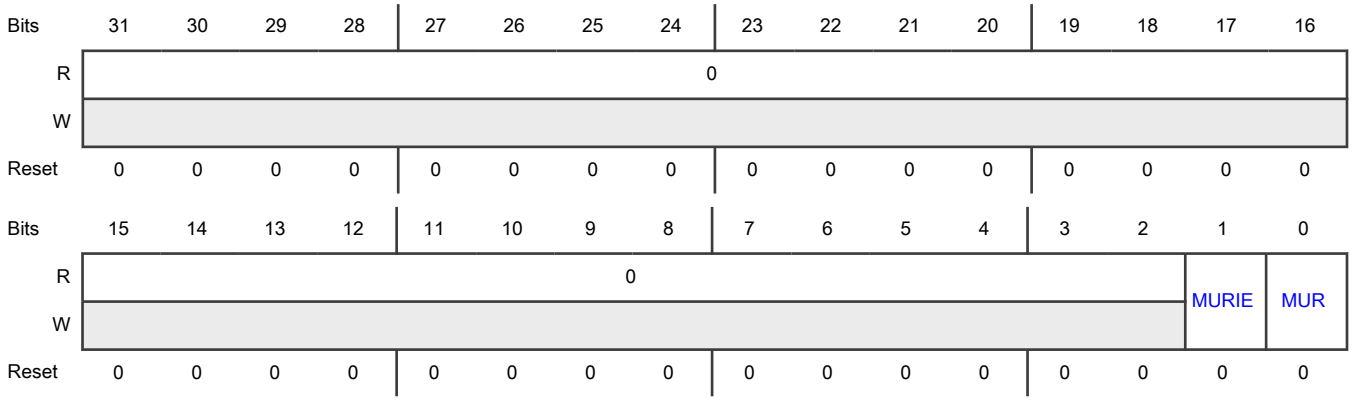
Offset

Register	Offset
CR	8h

Function

Controls MU reset and reset interrupt enable.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 MURIE	MUB Reset Interrupt Enable Enables the processor B-side MU reset interrupt request due to MU reset issued by MUA. If the value of this field is 1, an MU reset interrupt request is issued to processor B when MUB_SR[MURIP] = 1. If the value of this field is 0, MU ignores the value of MURIP and issues no MU reset interrupt request. Only a system reset can reset this field. CR[MUR] cannot reset this field. 0b - Disable 1b - Enable
0 MUR	MU Reset Resets MU. Writing 1 to this field resets the MUB and MUA sides. All internal states are cleared. It forces all control and status registers to return to their default values (except in MUB/A_CCR0 registers; MURIE in MUB/A_CR registers; MURIP and MURS in MUB/A_SR registers). Before writing 1 to this field, interrupt processor A because writing 1 to this field may affect the ongoing processor A program. After writing 1 to this field, monitor the value of MUB_SR[MURS] to know when the reset sequence on the processor A-side has ended. This field always reads 0, and it becomes 0 during the MU reset sequence. 0b - Idle 1b - Reset

40.7.2.5 Status (SR)

Offset

Register	Offset
SR	Ch

Function

Shows the status of MU resets and the status of pending events and requests.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								0	RFP	TEP	GIRP	FUP	EP	MURIP	MURS
W															W1C	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	u

Fields

Field	Function
31-8 —	Reserved
7 —	Reserved
6 RFP	MUB Receive Full Pending Indicates whether a receive full message is pending. This field becomes 1 when MUA writes to a TR*n* register to send data to MUB. After this field becomes 1, MU checks RSR[RF*n*] to determine whether the data in the Receive register is ready for MUB to read it. This field becomes 0 when all MUB RR*n* registers are read, or when MU is reset. 0b - Not pending; MUA is not writing to a Transmit register 1b - Pending; MUA is writing to a Transmit register
5 TEP	MUB Transmit Empty Pending Indicates whether a transmit empty message is pending.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 when any TCR[TIE*n*] field is 1 and MUA reads the corresponding Receive (RR*n*) register. After this field becomes 1, MU checks TSR[TE*n*] to determine whether the data in the Transmit (TR*n*) register is ready for MUB to write to it. This field becomes 0 when write operations to all MUB Transmit (TR*n*) registers where TCR[TIE*n*] = 1 (transfer interrupt enabled) are completed, or when MU is reset. 0b - Not pending; MUA is reading no Receive (RRn) register 1b - Pending; MUA is reading a Receive (RRn) register
4 GIRP	MUB General-Purpose Interrupt Pending Indicates that MUA has sent a general-purpose interrupt request. This field becomes 1 when the MUA side sends a general-purpose interrupt request to the MUB side. GSR[GIP*n*] identifies which general-purpose interrupt request is received. This field becomes 0 when all MUB_GSR[GIP*n*] fields are cleared, or when MU is reset. 0b - No request sent 1b - Request sent
3 FUP	MUB Flag Update Pending Indicates whether a flag update request is pending. MU generates this request when there is a change to the F*n*[31:0] bits of MUB_FCR. This field becomes 1 when the MUB side sends a flag update request to the MUA side. This field becomes 0 when MU acknowledges this flag update request internally (the flag is updated) from the MUA side, or during MU reset. No flag update changes are allowed when this field is 1. When FUP = 1, a write to the F*n*[31:0] bits of MUB_FCR does not generate a flag update event. The F*n*[31:0] bits do not change. If SR[EP] = 1 (event pending), writing to MUB_FCR does not immediately cause this field to become 1. 0b - No pending update flags (initiated by MUB) 1b - Pending update flags (initiated by MUB)
2 EP	MUB Side Event Pending Indicates a pending side event when the MUB side sends an event update request to the MUA side. An event is any hardware message that the Status register on the MUA side reflects. For example, an event occurs when Transmit register 0 is the target of a write operation. During normal operations, the update mechanism for this field operates automatically. MU clears this field automatically when the event update acknowledgment is received, or when MU resets. To ensure that events are posted to MUA, verify that this field is 0. If it is 1, wait and continue to poll this field until it becomes 0. 0b - Not pending 1b - Pending
1	MU Reset Interrupt Pending Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
MURIP	Indicates whether processor A has issued an MU reset. This flag is set after processor A initiates an MU reset by setting MUB_CR[MUR]. If CR[MURIE] = 1, the processor B MU reset interrupt request is issued when processor A writes 1 to MUA_CR[MUR]. Clearing this flag also clears the MU reset interrupt request. Only a system reset can reset this flag. MU reset cannot reset this flag. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Reset not issued 1b - Reset issued When writing 0b - No effect 1b - Clear the flag
0 MURS	MUA and MUB Reset State Indicates the reset state of MUA and MUB. This field becomes 1 during any system reset or MU reset from the MUA or MUB side. This field becomes 0 when the reset sequence on both MUA and MUB sides ends. After issuing any of the aforementioned reset events, verify that this field is 0 before starting any access. 0b - Out of reset 1b - In reset

40.7.2.6 Core Control 0 (CCR0)

Offset

Register	Offset
CCR0	10h

Function

Allows MUB to control the processor on the MUA side.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
MU_0.MUB	CCR0	—
MU_1.MUB	CCR0	—
MU_2.MUB	—	CCR0
MU_3.MUB	—	CCR0
MU_4.MUB	—	CCR0

4 —	Reserved
3 —	Reserved
2 —	Reserved
1 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 NMI	MUA Nonmaskable Interrupt Request Indicates whether Processor B has issued a nonmaskable interrupt to Processor A. When this field becomes 1, it initiates a nonmaskable interrupt to processor A. This field becomes 0 after 1 is written to MUA_CSSR0[NMIC] to clear that field. After this field becomes 0, MUB can initiate another nonmaskable interrupt to MUA. This field is cleared when MU resets. 0b - Nonmaskable interrupt not issued 1b - Nonmaskable interrupt issued

40.7.2.7 Core Sticky Status 0 (CSSR0)

Offset

Register	Offset
CSSR0	18h

Function

Shows the status of interrupts pending (W1C).

The reset value is chip-specific.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
MU_0.MUB	CSSR0	—
MU_1.MUB	CSSR0	—

When MUA_FCR[F*n*] is written to, the write event updates MUB_FSR[F*n*], after the event update latency. 0b - MUA_FCR[Fn] = 0 1b - MUA_FCR[Fn] = 1
0 F0	MUA to MUB-Side Flag Contains flags configured by the values written to MUA_FCR[F*n*], where *n* = 0 to 31. F*n* is the MUB-side flag configured by the values written to MUA_FCR[F*n*]. When MUA_FCR[F*n*] is written to, the write event updates MUB_FSR[F*n*], after the event update latency. 0b - MUA_FCR[Fn] = 0 1b - MUA_FCR[Fn] = 1

40.7.2.10 General-Purpose Interrupt Enable (GIER)

Offset

Register	Offset
GIER	110h

Function

Contains the MUB general-purpose interrupt enable fields.

Fields

Field	Function
31 GIR31	MUB General-Purpose Interrupt Request Specifies whether general-purpose interrupts are requested to MUA. There are 32 general-purpose interrupts (*n* = 0 to 31). Writing 1 to GIR*n* sets MUA_GSR[GIP*n*]. If MUA_GIER[GIE*n*] = 1, a general-purpose interrupt request is triggered on processor A. This field becomes 0 when MUA_GSR[GIP*n*] is cleared. This clearing informs MUB that the interrupt is accepted (cleared by software). To ensure proper operations, verify that GIR*n* is 0 (no pending interrupt) before writing 1 to it. This field becomes 0 when MU resets. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

GIR12

MUB General-Purpose Interrupt Request

Specifies whether general-purpose interrupts are requested to MUA. There are 32 general-purpose interrupts (*n* = 0 to 31).

Writing 1 to GIR*n* sets MUA_GSR[GIP*n*]. If MUA_GIER[GIE*n*] = 1, a general-purpose interrupt request is triggered on processor A.

This field becomes 0 when MUA_GSR[GIP*n*] is cleared. This clearing informs MUB that the interrupt is accepted (cleared by software).

To ensure proper operations, verify that GIR*n* is 0 (no pending interrupt) before writing 1 to it.

This field becomes 0 when MU resets.

NOTE

This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in

GIPn informs MUB that MUA_GCR[GIRn] changed from 0 to 1. If MUB_GIER[GIEn] = 1, a general-purpose interrupt request is issued to processor B.

GIPn is cleared when MU resets.

After GIPn is cleared, if MUB_GIER[GIEn] = 1, the general-purpose interrupt request is cleared on the MUB side.

NOTE
This field behaves differently for register reads and writes.

Chapter 41
Power Management

41.1 Introduction

The power management system generates, monitors, and controls power supplies and related resets. This chapter describes the system's interaction with other peripherals.

The power management system includes the modules listed below.

Table 244. Power management system modules and their functions

Part	Function
MC_ME	Initiates entry into Low-Power mode
MC_PCU	Controls entry into and exit from Low-Power mode
PMC	Regulates and monitors power supplies of the Run and the Standby domains
MC_RGM	Ensures a clean state and correct Run domain functionality by controlling the reset sequence
FIRC, WKPU, and other chip peripherals	Controls Standby mode wake-up and operations in Run and Standby modes

41.1.1 Power management system for S32K344, S32K324, S32K314, S32K341, S32K342, and S32K322

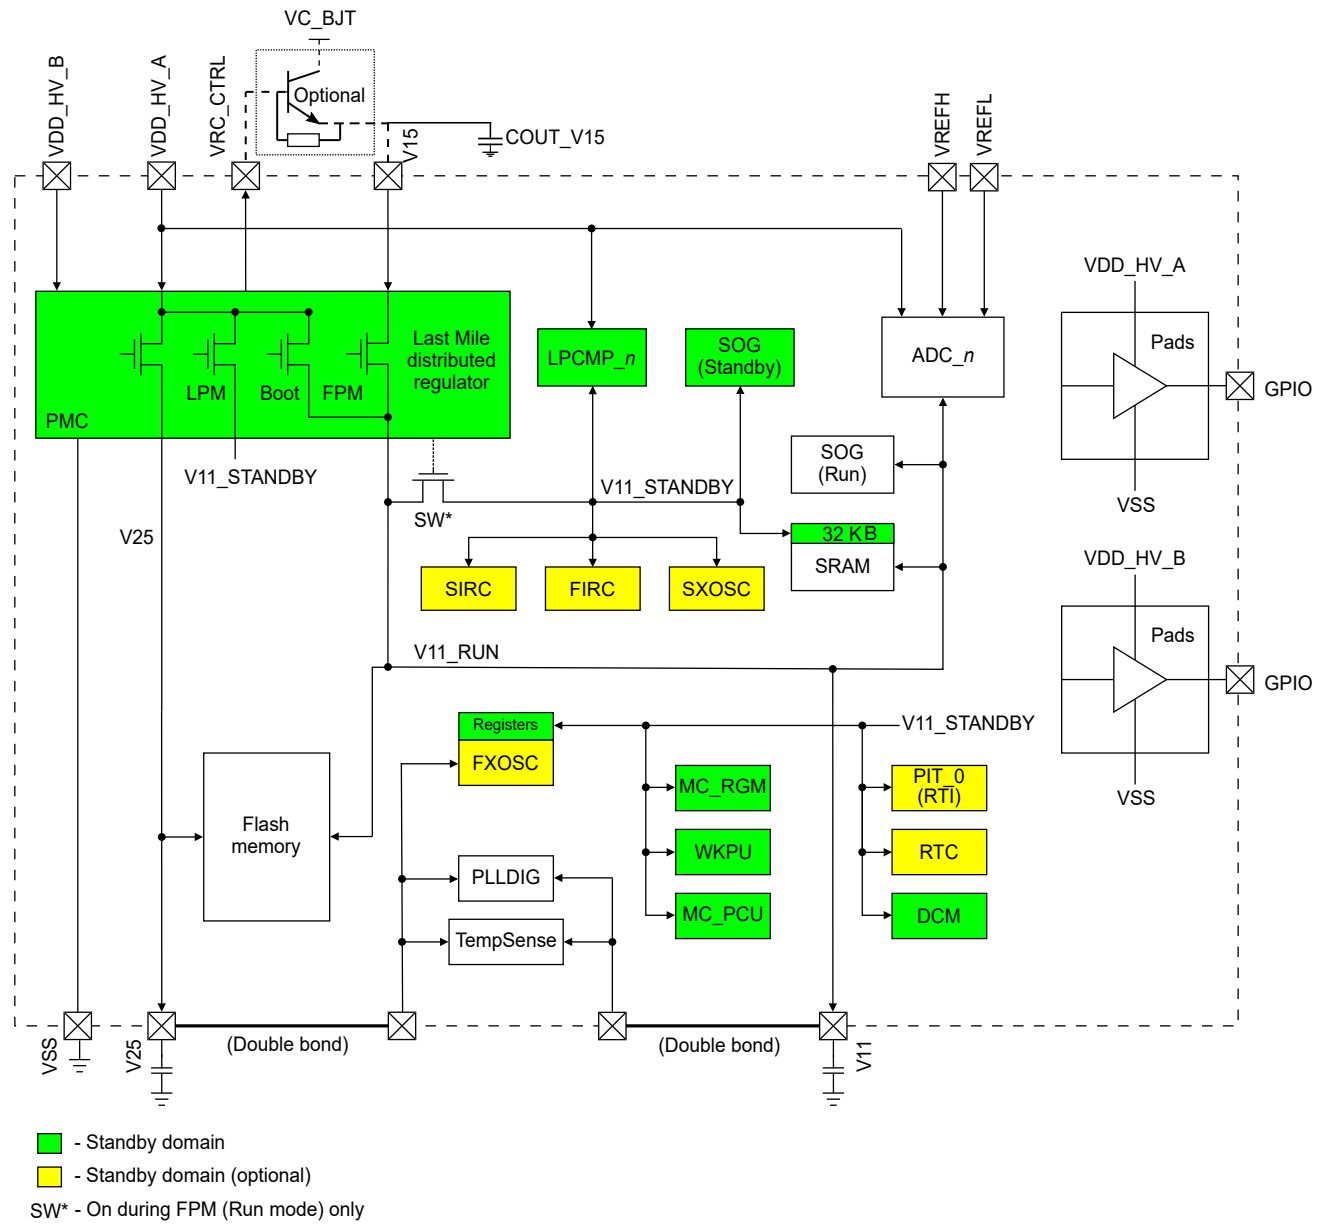

Figure 169. Power management system for S32K344, S32K324, S32K314, S32K341, S32K342, and S32K322

41.1.2 Power management system for S32K312 and S32K311, and S32K310

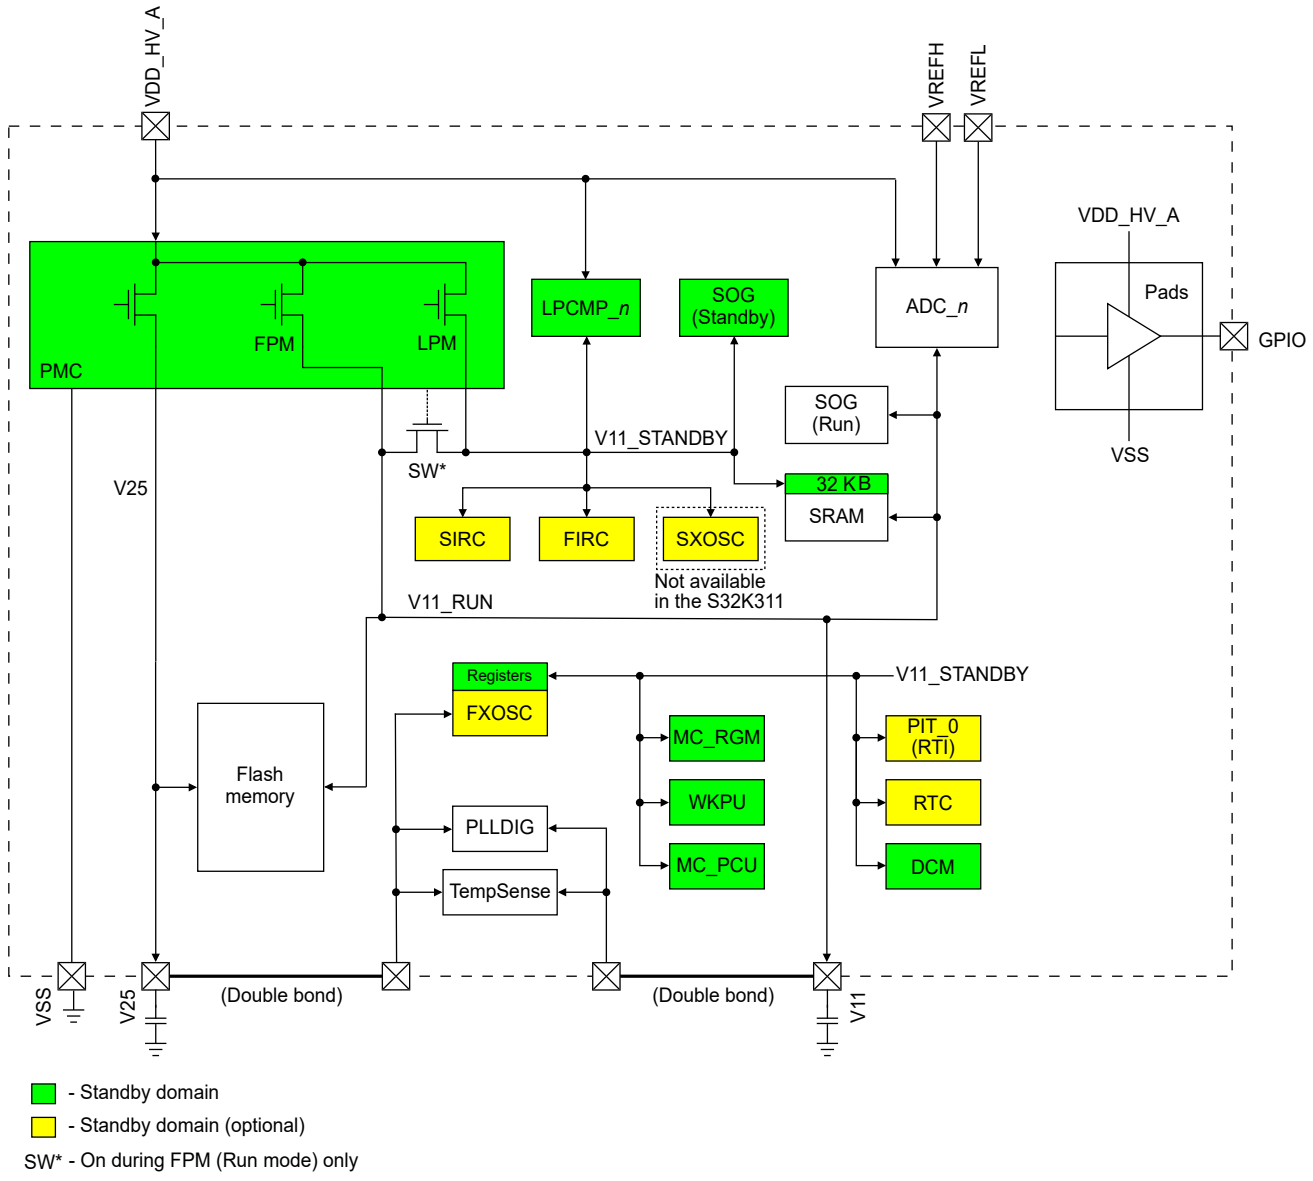

Figure 170. Power management system for S32K312 and S32K311, and S32K310

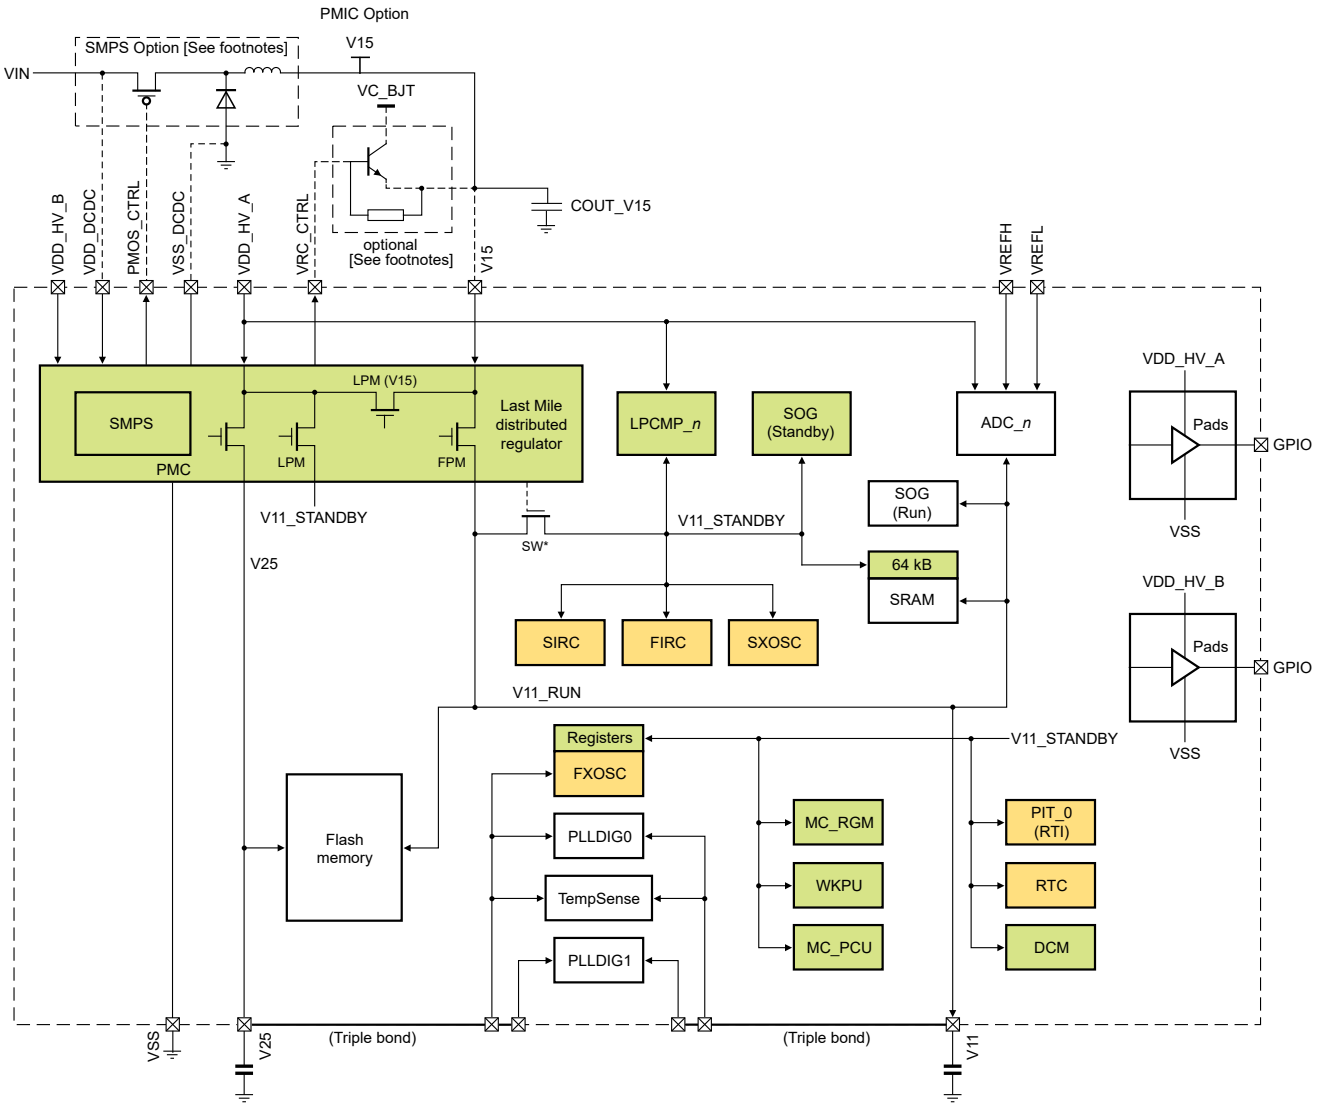
41.1.3 Power management system for S32K358/S32K348/S32K338/S32K328



SW* - On during FPM (Run mode) only

The V15 input voltage can be supplied directly by an SBC or Voltage regulator. The S32K3x8 devices provide two options to derive the V15 regulator from the 5V or 3.3V supply.

Option 1: A DC/DC converter (SMPS) regulator can be implemented by connecting the external components (PMOS, inductor, diode) shown in the figure above, at pins VDD_DCDC, PMOS_CTRL, and VSS_DCDC. In this case, VRC_CTRL must not be connected. VDD_DCDC must be connected to the VDD_HV_A or VDD_HV_B, supply voltage. In this option COUT_V15 is specified in SMPS regulator electrical specifications.

Option 2: A linear regulator can be implemented by connecting a bipolar NPN transistor from the VDD_HV_A or VDD_HV_B, supply voltage shown as VC_BJT in the figure above. The VRC_CTRL pin must be connected to the base of the transistor. In this case, VDD_DCDC, PMOS_CTRL must not be connected. VSS_DCDC must be connected to MCU GND. In this option, COUT_V15 is specified in Recommended decoupling capacitors.

Note: In the EP package, you must connect the exposed pad to ground (VSS).

Figure 171. Power management system for S32K358/S32K348/S32K338/S32K328

41.1.4 Power management system for S32K388/S32K389

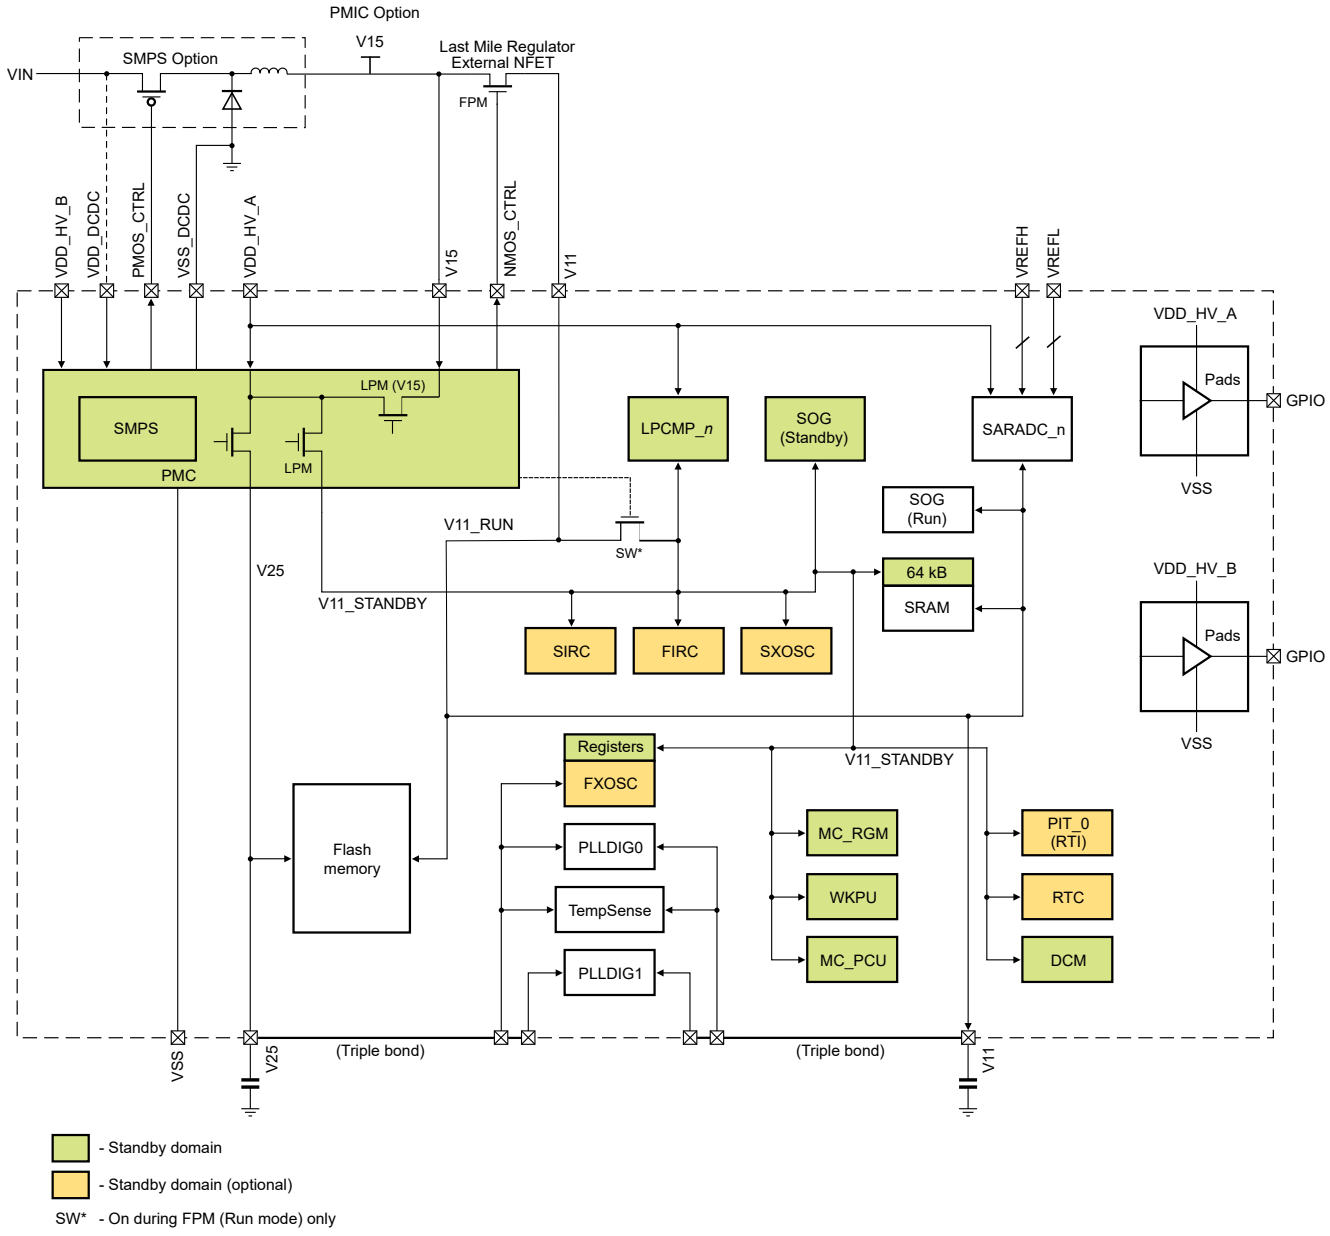


Figure 172. Power management system for S32K388/S32K389

41.1.5 Features

- For S32K310, S32K311, S32K312, PMC uses VDD_HV_A to generate 1.1 V (nominal) supply for the core logic (V11_RUN).
- For other chips, PMC uses a 1.5 V supply to generate 1.1 V (nominal) supply for the core logic (V11_RUN).
- S32K358/S32K348/S32K338/S32K328, S32K342/S32K322/S32K341, S32K344/S32K324/S32K314 includes a linear regulator to use an optional external ballast (BJT) and VRC_CTRL output for 1.5 V generation.
- Supports a low-power regulator (LPM) supplying core logic during Standby mode (V11_STANDBY)
- Includes 1.1 V FPM regulator options for driving the logic in RUN mode (V11_RUN) from a 1.5V supply:

  - Boot LDO for S32K344/S32K324/S32K314, S32K342/S32K322/S32K341
  - Internal Last-mile (FPM) for S32K344/S32K324/S32K314, S32K342/S32K322/S32K341, S32K358/S32K348/S32K338/S32K328
  - External Last-Mile (FPM) for S32K388/S32K389
- Supports power switches to isolate voltage islands and configure the chip in Standby mode
- S32K358/S32K348/S32K338/S32K328/S32K388/S32K389 supports a DC-DC buck converter stage, with a dedicated pin to control an external Power MOSFET, in the range from 1.4V to 1.5V.
- S32K388/S32K389 controls an external NMOS transistor, and uses V15 generated from SMPS as input to generate V11 for a load current up to 1.5 A (disabled in Standby mode).
- Includes a linear regulator that generates a 2.5 V supply (V25) from VDD_HV_A
- Supports voltage monitors ensuring transitions to a safe state (POR) when a supply is out of a valid range
- Controls power-mode transitions through an interaction with the digital interface
- Offers a padkeeping feature that retains PAD state during standby mode till software boots up
- Provides separate ADC reference supplies (VREFH and VREFL)

41.1.6 Operational power modes

This chip has two power modes:

- Run mode (FPM): Main operation mode with full chip performance and a higher current consumption as compared to Standby mode.
- Standby mode (LPM): Low-performance mode of the chip in which the Run domain is turned off. The cores and most peripherals are off in this mode.

The boot regulator manages the chip during the booting process except S32K3x8, S32K312, S32K311 and S32K310.

The last-mile regulator is the full-performance regulator, which you enable for running applications. The upcoming sections discuss the sequence to enable or disable the regulator.

The LPM regulator manages the chip in Standby mode.

41.1.7 External 1.5 V source

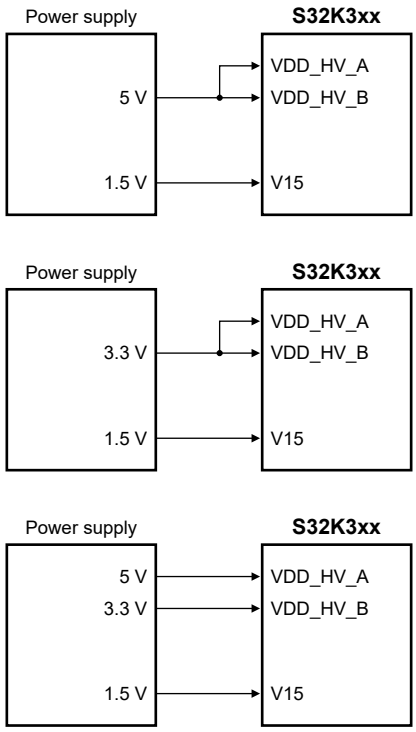

Figure 173. Core supply from external 1.5 V source (except for S32K388, S32K389, S32K312, S32K311, S32K310)

41.1.8 External 1.5 V source (applicable for S32K388/S32K389)

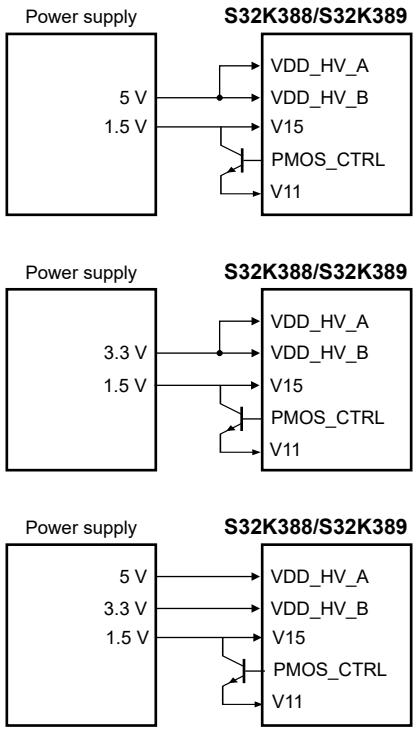

Figure 174. Core supply from external 1.5 V source, with external last-mile regulator (applicable for S32K388/S32K389)

41.1.9 Using a BJT for 1.5 V generation (not applicable for S32K388, S32K389, S32K312, S32K311, and S32K310)

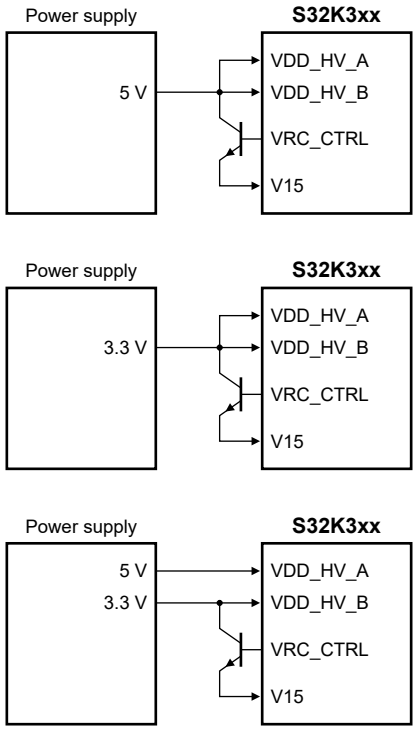

Figure 175. Using a BJT for 1.5 V generation

41.2 Power-up sequence

Figure 176 shows the reset sequence for a power-up or Standby mode event. This sequence starts from the POR phase. For the Run domain logic, Standby mode exit operation is same as power-up.

See the "Reset Overview" chapter for more information about the chip reset sequence.

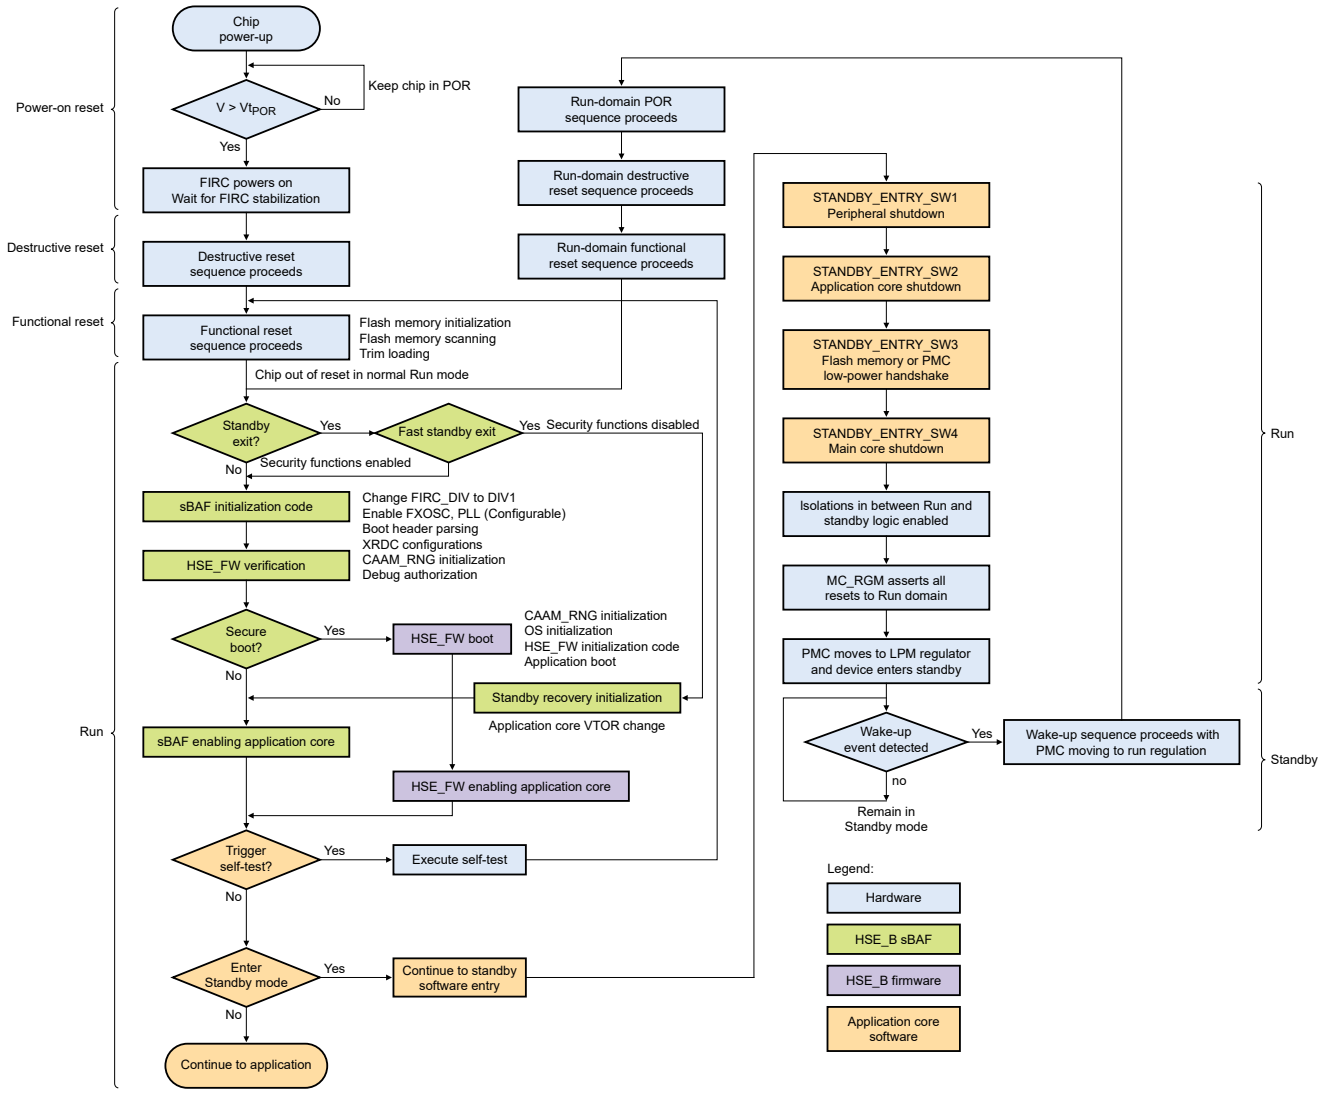

Figure 176. Power-up sequence

41.3 PMC last-mile regulator auto-enable feature (applicable for S32K344, S32K324, S32K314, S32K341, S32K342, and S32K322)

PMC includes an automatic last-mile auto-enable feature. After starting on boot regulator, this feature allows automatic switch over to last-mile regulator if 1.5 V is present during:

- Chip startup
- Standby mode recovery

You can control the PMC last-mile regulator by appropriately configuring:

- PMC.CONFIG[LMAUTOEN] field
- PMC.CONFIG[LM_EN] field

  For more information, see the descriptions of these fields in PMC.CONFIG register.

NOTE

You must write 1 to PMC.CONFIG[LM_EN] field before transtioning to faster clock frequencies irrespective of the setting of PMC.CONFIG[LMAUTOEN] field. This is because of the reduced clock speed when using the boot regulator.

41.3.1 Last-mile regulator with 1.5 V from an external source (applicable for S32K344, S32K324, S32K314, S32K341, S32K342, and S32K322)

Table 245. Last-mile regulator with 1.5 V from an external source

Operating condition	Last-mile regulator operation
After POR	Boots on boot regulator and then automatically switches to the last-mile regulator
After destructive reset	Remains on last-mile regulator **NOTE** If the destructive reset source is low voltage reset on 1.1 V then switchback happens from last-mile to boot regulator for boot.
After functional reset	Remains on last-mile regulator
After PMC.LVSC[LVD15S] field becomes 1	Switches, automatically, to the boot regulator to configure clocks for slow speed

41.3.2 Last-mile regulator using a BJT (applicable for S32K344, S32K324, S32K314, S32K341, S32K342, and S32K322)

Table 246. Last-mile regulator using a BJT

Operating condition	Last-mile regulator operation
After POR	Boots on boot regulator; switches to the last-mile regulator post reset when the Cortex-M7 core configures the software on FIRC
After destructive reset	Switches to boot regulator to check reset propagation delay
After functional reset	Remains on last-mile regulator
After PMC.LVSC[LVD15S] field becomes 1	Switches, automatically, to boot regulator to configure clocks for slow speed

41.4 PMC last-mile regulator auto-enable feature (applicable for S32K358, S32K348, S32K338 and S32K328)

PMC includes an automatic last-mile auto-enable feature.

You can control the PMC last-mile regulator by appropriately configuring:

- PMC.CONFIG[LMAUTOEN] field
- PMC.CONFIG[LM_EN] field

  For more information, see the descriptions of these fields in PMC.CONFIG register.

41.4.1 Last-mile regulator with 1.5 V from an external source (applicable for S32K358, S32K348, S32K338 and S32K328)

Table 247. Last-mile regulator with 1.5 V from an external source

Operating condition	Last-mile regulator operation
After POR	Waits for 1.5 V to start last-mile regulator
After destructive reset	Remains on last-mile regulator
After functional reset	Remains on last-mile regulator

41.4.2 Last-mile regulator using a BJT (applicable for S32K358, S32K348, S32K338 and S32K328)

Table 248. Last-mile regulator using a BJT

Operating condition	Last-mile regulator operation
After POR	Wait for 1.5 V, if it is at sustained level, PMC starts the last-mile regulator
After destructive reset	Remains on last-mile regulator
After functional reset	Remains on last-mile regulator

41.5 Standby mode entry sequence

The Standby mode entry sequence includes three phases of operation:

- Standby mode entry configuration phase or software Standby mode entry sequence
- Standby mode entry handshake phase or hardware Standby mode entry sequence
- Standby mode entry or PMC Standby mode entry

NOTE

The Standby mode entry sequence described in this section is the only supported sequence. Contact NXP support if you require an alternate Standby mode entry sequence.

NOTE

In S32K388/S32K389, after triggering Standby Entry from Application, if Reset is asserted before Standby entry then reset can be issued to system, which will be visible at RESET_B pad.

NOTE

When "PMIC Handshake with MCU" is not used, to be able to exit from STANDBY mode, PMIC_PGOOD_HNDSHK_BYP must be set to 1.

41.5.1 Software Standby mode entry sequence

The Standby mode entry sequence includes chip configuration as described in the following sections.

Before entering the software Standby mode sequence, the system clock source must be changed to FIRC at 48 MHz because PLLDIG is not available in Standby mode. In Standby mode, all clock sources can be optionally disabled (including FIRC, which results in a no-clock, low-power consumption mode). You could also use FXOSC, if enabled, when the 2.5 V supply is available by appropriate configuration of PMC.CONFIG[LPM25EN].

The software Standby mode entry sequence consists of four steps:

1. SW1: Module shutdown process
2. SW2: Application core shutdown process

3. SW3: Flash memory low-power handshake and PMC last-mile regulator control[9]
4. SW4: Main core shutdown process

These processes are described in detail in the sections that follow. See Figure 176 that shows the relationship between these four steps in a flow diagram.

41.5.1.1 SW1: Module shutdown process

I/O and module configuration for Standby mode discusses the procedure to configure I/O and the chip modules for Standby mode.

The entry sequence for this mode includes module clock disabling steps (see the "Clocking" chapter for module clock turn on and turn off processes). You must use MC_ME.PRTN*n*_COFB*m*_CLKEN[REQ*p*] fields to enable or disable module clocks.

41.5.1.1.1 Disabling modules

Disable modules by configuring the appropriate fields in their registers for Standby mode operation. See specific module chapters for more information.

The Standby mode entry sequence includes the module clock disabling step, with which you can disable the modules that you do not need for Standby mode operation.

The sequence of disabling modules is shown in I/O and module configuration for Standby mode.

NOTE

While enabling or disabling the modules, you must verify that the module is disabled when you read MC_ME.PRTNn_COFBm_STAT register and the module disable field, if applicable. In case of a discrepancy, you must perform proper diagnostic steps.

You must clear the I/O controls for the pads that you do not require in Standby mode (OBE, IBE, and so on). This avoids any unwanted pad keeping settings. See Pad keeping for more information on the chip pad keeping process.

For any standby wake source, if an interrupt occurs it must be disabled before entering Standby mode and only the wake up event of that source must be enabled. This is to avoid any SW conflict in the interrupt handling for multi application core cases.

The MC_ME.PRTN*n*_COFB*m*_STAT register indicates the status of peripheral clock enable or disable. It may take up to three clock cycles for MC_ME.PRTN*n*_COFB*m*_STAT register to update after MC_ME.PRTN*n*_COFB*m*_CLKEN register is updated.

Once modules are disabled by following above steps:

- Switch to FIRC as the system clock.
- Disable FXOSC and wait for clock status.
- Configure Standby Entry.

[9] Not applicable for S32K388/S32K389.

41.5.1.1.2 I/O and module configuration for Standby mode

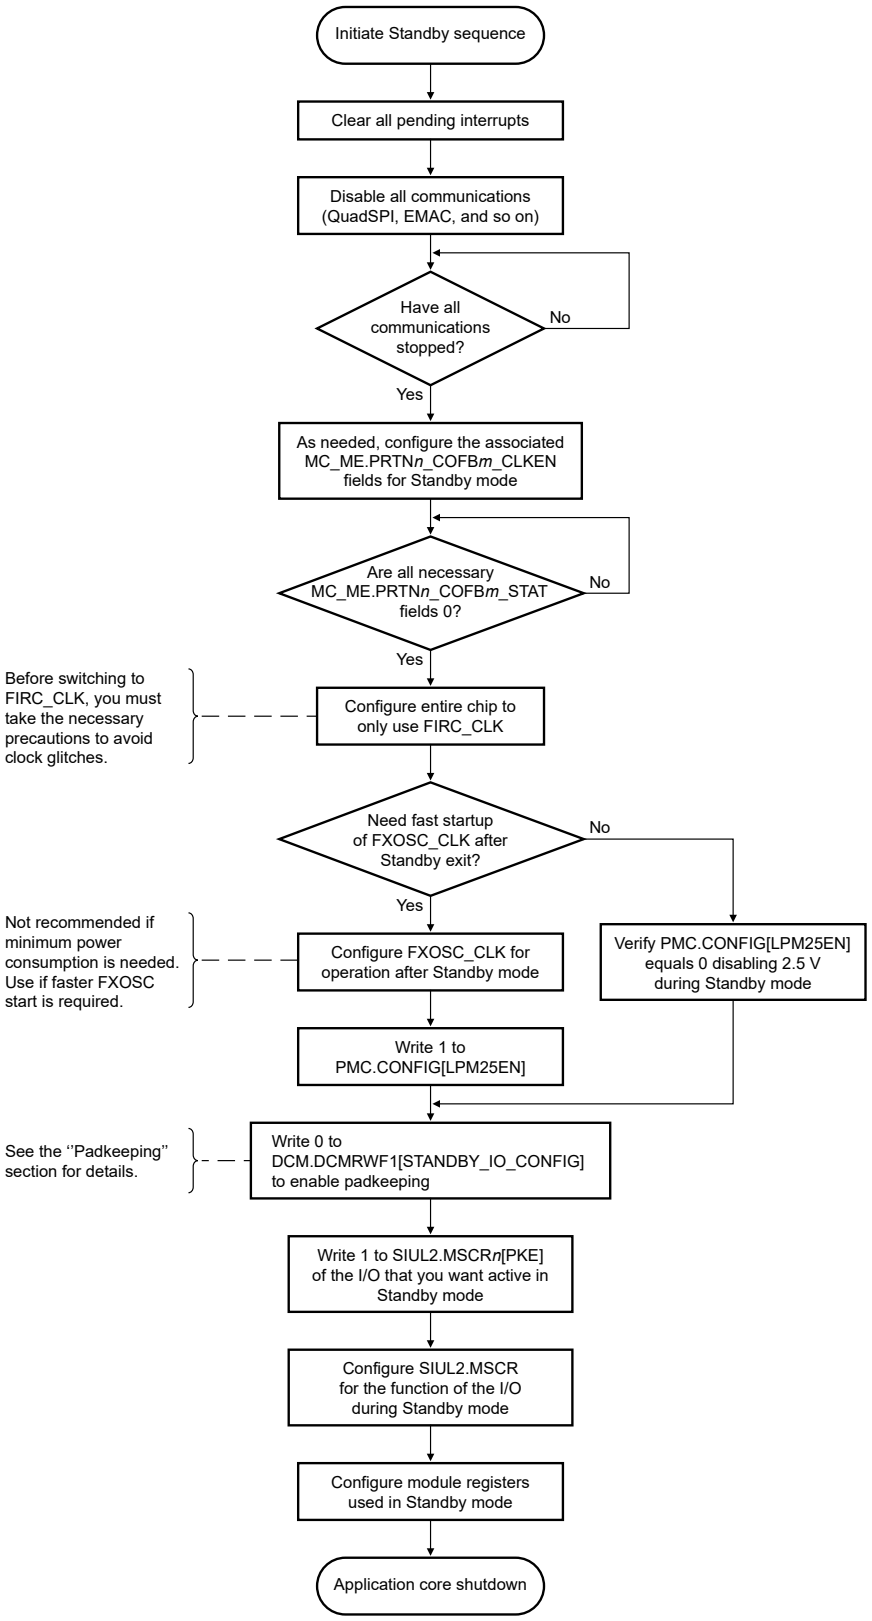

Figure 177. I/O and module configuration for Standby mode

41.5.1.2 SW2: Application core shutdown process

The application cores(s) execute a WFI (as opposed to the main core running the Standby mode entry sequence). See the section "Application core shutdown" in the MC_ME chapter for more information.

The main core configuration (programming valid core ID and enabling standby entry process) and wake-up source configuration must also be set in SW2, so that SW4 contains only the main core WFI execution.

41.5.1.3 SW3: Flash memory low-power handshake and PMC last-mile regulator

In this process, you execute a flash memory low-power handshake and disable the PMC last-mile regulator by executing the procedures indicated in Figure 178 and Figure 179.

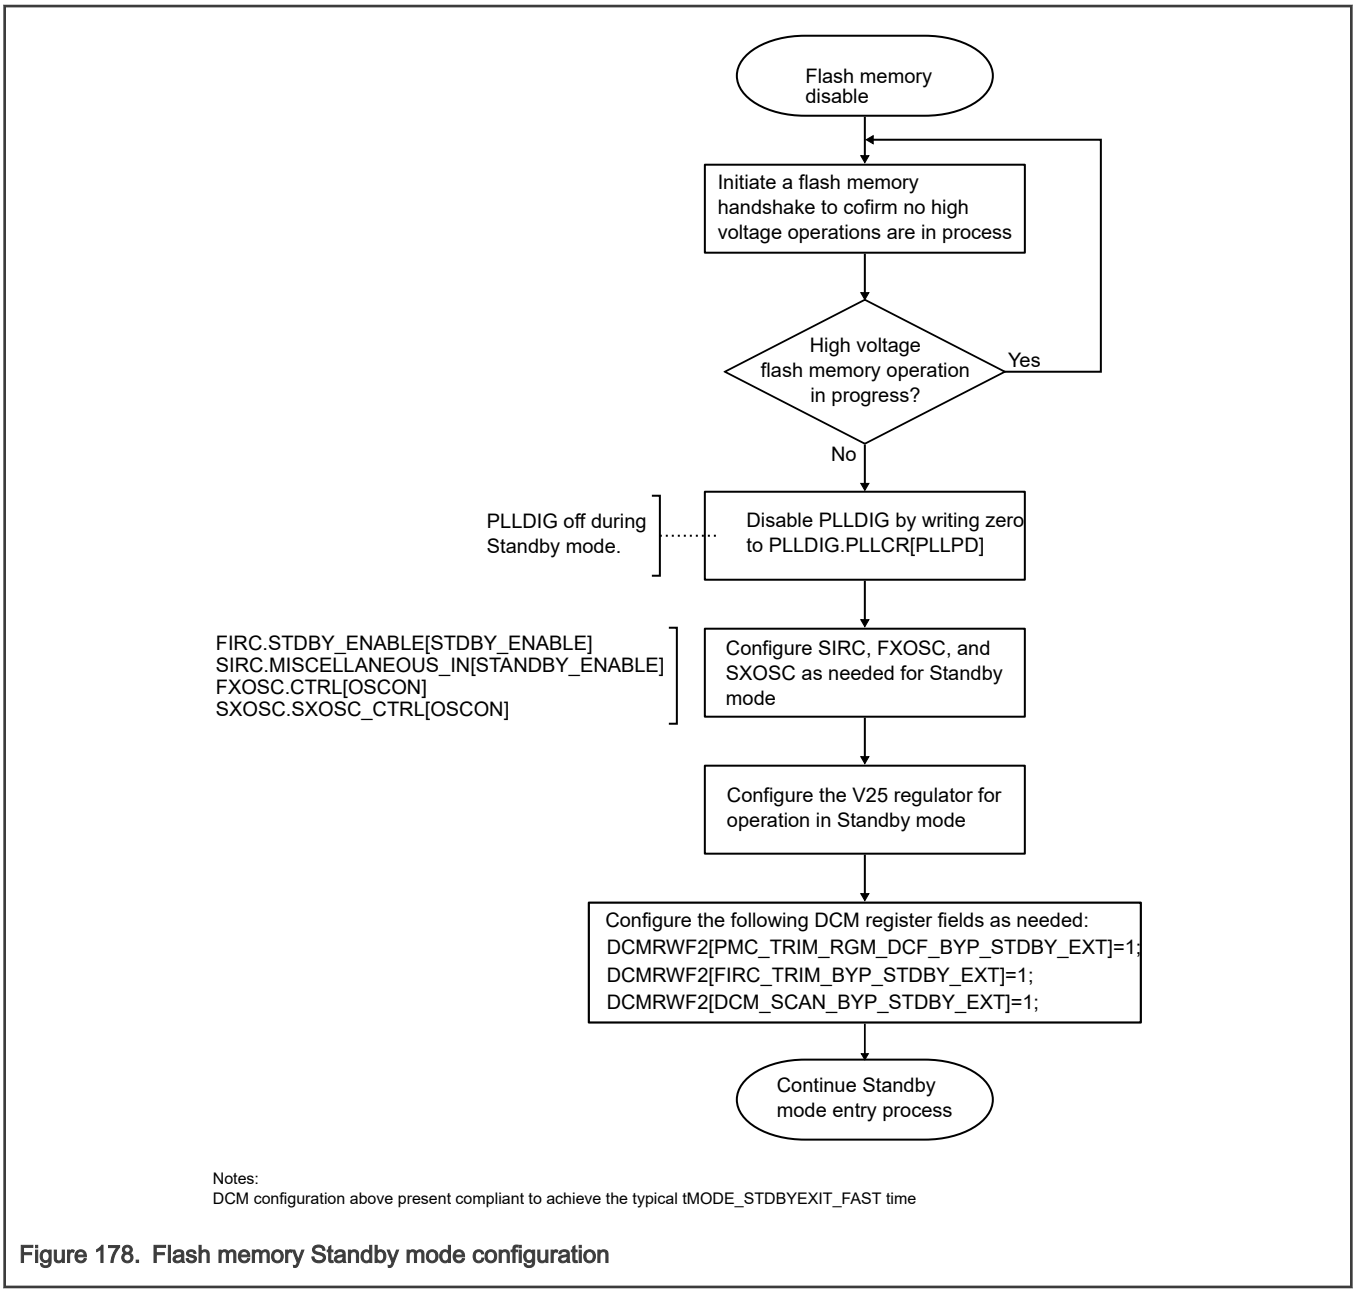

Figure 178. Flash memory Standby mode configuration

NOTE

Disable the last-mile regulator according to the Last-mile regulator disable sequence (not applicable for S32K3x8, S32K312, S32K311 and S32K310).

41.5.1.3.1 Last-mile regulator disable sequence (not applicable for S32K3x8, S32K312, S32K311 and S32K310)

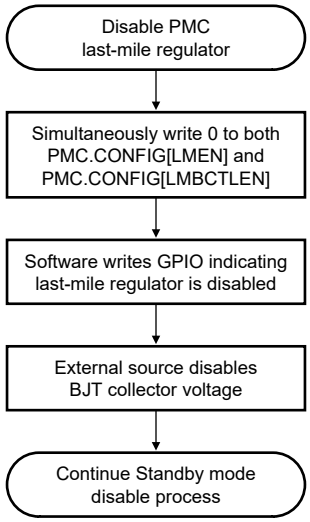

Figure 179. Last-mile regulator disable sequence

When exiting Standby mode, the 1.1 V capacitor is charging. You can charge the 1.5 V capacitor during or after the 1.1 V capacitor is charged. If you charge the 1.5 V capacitor sequentially after the 1.1 V capacitor, you will need additional time to complete the overall charging process.

Leaving PMC.CTRL[LMBCTLEN] = 1 saves time when exiting Standby mode and does not draw any additional current during this mode.

41.5.1.4 SW4: Main core shutdown process

For information on this process, see these in the "Mode Entry Module (MC_ME)" chapter:

- Figure "Standby entry sequence along with main core shutdown"
- Section "Main core shutdown and Standby mode entry"

You must configure WKPU before disabling interrupts to avoid missing any events as shown in the Standby entry sequence along with main core shutdown flowchart in the MC_ME chapter. You must program WKPU, disable interrupts, and configure MC_ME's Standby mode entry in SW1 (see SW1: Module shutdown process for more information). In SW4, you must perform only the main-core WFI execution.

41.5.2 Hardware Standby mode entry sequence

The hardware Standby mode entry sequence consists of handshaking between MC_PCU and MC_ME occurring after Software Standby mode entry sequence completes. The FSM in MC_PCU performs these steps automatically and does not require your intervention (see Power sequence FSM in the MC_PCU chapter for more information).

During the MC_ME and PCU phase, MC_ME and PCU:

- Enable FIRC.
- Deassert isolation.
- Deassert reset to PD1.

41.5.3 PMC Standby mode entry

The PMC Standby mode entry sequence starts after Hardware Standby mode entry sequence completes, and consists of these phases:

1. Standby mode entry acknowledgment and initiation of an internal low-power process on receiving Standby mode entry request.
2. Disabling of the boot regulator within the PMC low-power process. This point is only applicable for S32K344/S32K324/S32K314 and S32K342/S32K322/S32K341.
3. Disabling of the V25 regulator and the FPM LVR monitors.
4. Disabling of the V25 regulator (oscillator and flash memory supply) and the LPM monitor, unless it is enabled during Standby mode (see PMC.CONFIG[LPM25EN] field in the PMC chapter for more information).
5. Disabling of the VDD_HV_B LPM monitors except S32K312, S32K311 and S32K310.

During PMC phase, after receiving an LPM request, PMC:

- Deasserts FPM ready signal.
- Starts the courtesy timer.
- When the courtesy timer expires, PMC:
  - Disables the V25 regulator.
  - Disables the HP reference blocks.
  - Disables the external NMOS.
  - Opens the PD0 switch.
  - Enables a core LPM request.
  - If selected, enables a 2.5 V LPM request.
  - Disengages FPM monitors.
  - Disables the VDD_HV_B LPM monitor, if present and deselected.
- Waits for LPM signal deassertion.

41.6 Chip status at the end of Standby mode entry sequence

After PMC Standby mode entry completes, the chip completes Standby mode entry as follows:

1. Configures Standby domain peripherals according to SW1 (see SW1: Module shutdown process).
2. Enables pad keeping on pins as described in SW1 (see SW1: Module shutdown process). See Pad keeping for other details.
3. Powers down all memory types except Standby RAM (in SRAM0).
   - The V25 regulator can remain on during Standby mode. However, for maximum power savings, it must remain off in this mode.
4. Isolates Standby and Run domains from each other:
   - Standby domain is functional.
   - Run domain is held in reset.
5. Configures the system clock (FIRC_CLK or PLL_PHI*n*_CLK, depending on their configuration) and other clock sources according to SW3 (see Figure 178 for the procedure details).

   The cores are off and in the Standby domain.
6. Turns off the boot[10] and FPM regulators.

7. Waits for a wake-up event to initiate recovery from Standby mode.

41.7 Chip operation in Standby mode

This chip supports the following functionalities in Standby mode:

- STANDBY_RAM content retention during Standby mode.
- Wake-up from up to 60 digital inputs (for details, see the signals WKUP[*n*] functions of WKPU module in the IOMUX file attached to this document). The section "Wakeup Unit Configurations" in the "Wakeup Unit (WKPU)" chapter shows mapping of the wake-up sources.
- Wake-up from up to 16 analog inputs through the Trigger mode functionality (see the signals CMP*n*_IN*m* functions of CMP*n* modules in the IOMUX file attached to this document).
- Wake-up from on-chip timers:
  - RTI (function of PIT[0])
  - SWT0
  - RTC
- Ability to configure the chip clocking modules to optionally enable or disable in Standby mode (FIRC, SXOSC, FXOSC, and SIRC).

41.8 Standby mode exit

This chip supports Standby mode exit from a wake-up, functional reset, or destructive reset event. The sources that cause chip Standby mode exit are:

- MC_RGM functional reset event
- MC_RGM destructive reset event
- WKPU wake-up events, WKPU[0]–WKPU[63]. See the WKPU chapter for more information.

After Standby mode exit, the following events occur (for more information, see "Power sequence FSM" in the MC_PCU chapter for MC_PCU FSM transitions during entry into and exit from Standby mode):

1. A wake-up event arrives.
2. FIRC starts powering up (if disabled in Standby mode).
3. PMC starts the transition process to FPM (for example, enables the last-mile regulator and provides V11_RUN supply to the chip).
4. MC_PCU removes the isolation between Run and Standby domains.
5. Run domain reset deasserts (asserts on Standby mode entry) and the chip undergoes a functional reset exit sequence for this domain.
6. The chip enters Run mode of operation.

NOTE

A reset event during standby results in pad controls to get reset. Thereby, resulting in unpredictable toggling at GPIO.

[10] Not applicable for S32K388, S32K389, S32K312, S32K311, and S32K310.

41.8.1 Faster Standby mode exit

The chip supports an optional configuration for faster recovery from Standby mode on the expense of a higher capacitor recharging current. See the CONFIG[FASTREC] field description in the PMC chapter for more information on faster PMC recovery from Standby mode.

This chip supports an optional feature that bypasses:

- FIRC trimming
- PMC trimming
- DCM scanning

To use the bypass operation, write 1 to DCM.DCMRWF2[5], DCM.DCMRWF2[4], and DCM.DCMRWF2[3] respectively before Standby mode entry. This results in a considerable reduction in Standby mode exit duration. The trim values are retained across Standby mode and bypassing these values does not cause any impact. Even if the FIRC trimming is bypassed, the FIRC must be at 48 MHz before entering Standby mode.

Configuration to achieve the tMODE_STDBYEXIT_FAST as specified in Datasheet

DCMRWF2[PMC_TRIM_RGM_DCF__BYP_STDBY_EXT] = 1

DCMRWF2[FIRC_TRIM_BYP_STDBY_EXT] = 1

DCMRWF2[DCM_SCAN_BYP_STDBY_EXT] = 1

41.8.2 Last-mile regulator enable sequence (not applicable for S32K388, S32K389, S32K312, S32K311 and S32K310)

After Standby mode exit, if the Last Mile Regulator Auto Enable function is not enabled, you must re-enable the PMC last-mile regulator before transitioning to faster clock frequencies. Figure 180 shows the last-mile regulator enable sequence part of the Standby mode exit process.

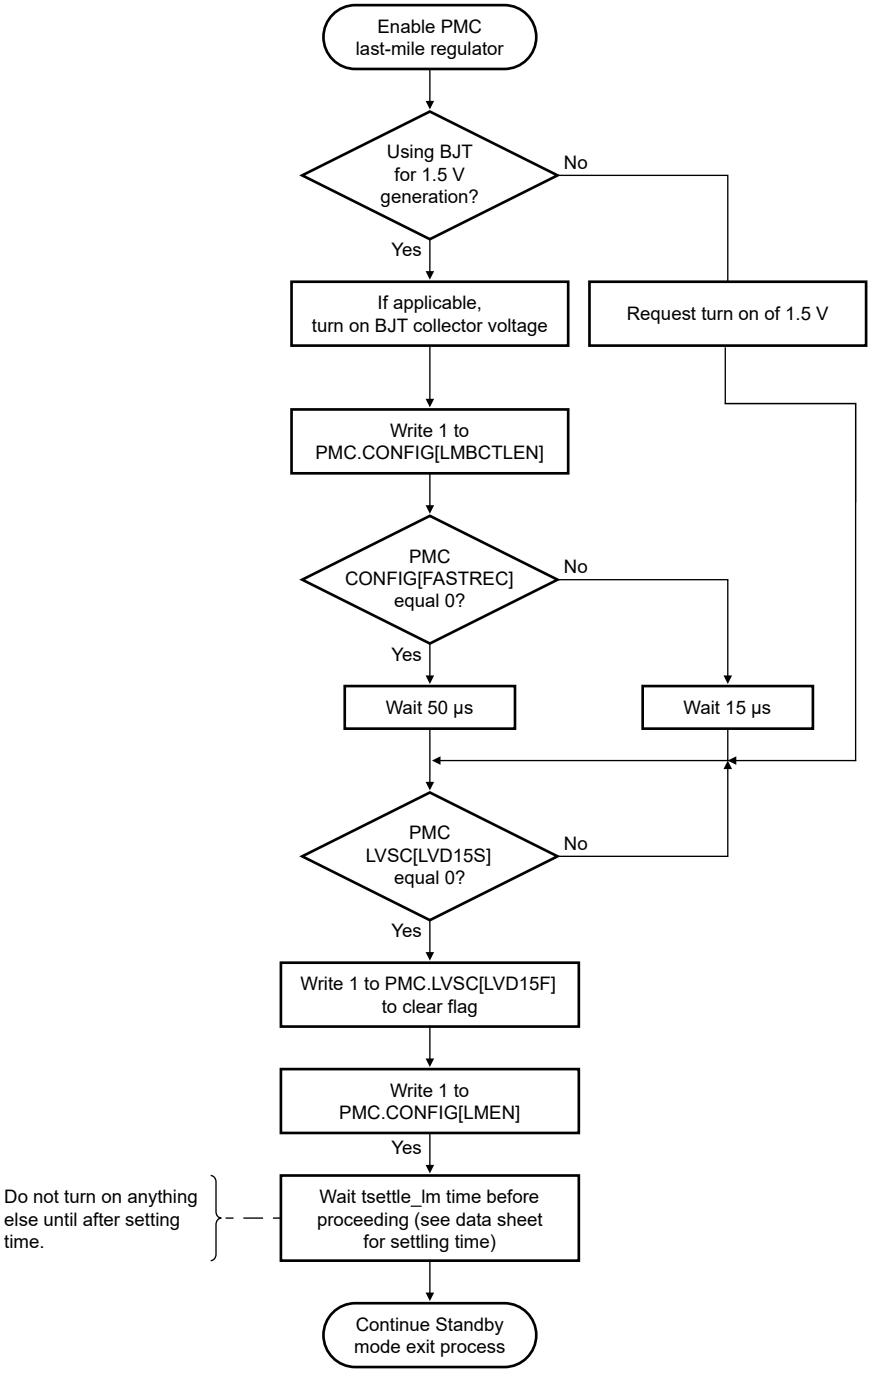

Figure 180. Last-mile regulator enable sequence

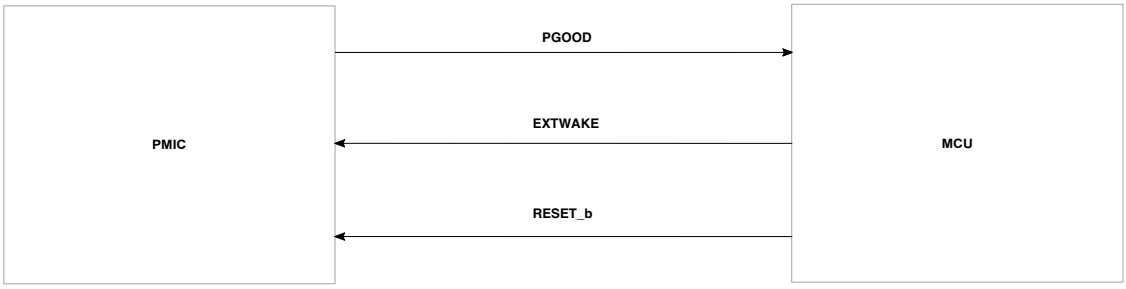
41.9 PMIC Handshake with MCU (applicable for S32K328, S32K338, S32K348, S32K358, S32K388, and S32K389)

For interfacing with PMIC where handshake is required, MCU will follow a sequence to come out of standby. This handshake will make sure that power supply to the MCU is in proper condition.

3 GPIOs will be used to perform this handshake as shown in below figure.

Figure 181. PMIC Handshake with MCU



MCU will assert EXTWAKE signal on receiving a wakeup request from any of the available wakeup sources. If the EXTWAKE signal is enabled via the MSCR configuration (see IOMIX file attached to this document), this wakeup will be triggered to the external PMIC and the PMIC will use it to come out of standby mode. MCU sends the reset_b signal to PMIC to reset the PMIC.

NOTE

After EXTWAKE assertion, POR WDOG is triggered. If PGOOD assertion does not arrive within the configured time, POR WDOG will issue a reset to the MCU.

PMIC will raise PGOOD signal towards MCU for indicating the MCU that it is now able to provide the supplies in proper conditions. If the PGOOD input is enabled via the corresponding IMCR configuration (see IOMIX file attached to this document) and the appropriate PGOOD polarity and enable settings are selected in the corresponding DCMRWF configuration registers (see PMIC_PGOOD_HNDSHK_BYP and PGOOD_POLARITY in Chapter 38, Device Configuration Module General-Purpose Registers (DCM_GPR)), the MCU will proceed to exit from STANDBY mode once the PGOOD input is asserted.

41.10 SMPS

SMPS is regarded as enhancement for the BJT regulator. The essential advantage of SMPS is that the power dissipation is much less compared to the linear regulators. SMPS generates the intermediate power rail of 1.5 V, which is then converted to 1.1 V by the last-mile regulator.

41.11 Chip power domain partitioning

The Standby domain includes the modules listed below. For more information, see "Peripheral reset status" in the "Reset Overview" chapter.

NOTE

Modules within the Standby domain do not participate in the LBIST operation.

41.11.1 Modules available in Standby domain

SWT0 (Cortex-M7_0) resides in the Standby domain and supports a configurable hardware-based timer operation during Standby mode depending on the configuration of SWTs.

All clock sources (except PLLDIG) are available in Standby mode. SIRC is present in the Standby domain for low-power wake-up, but can be enabled.

NOTE

This chip does not support Stop and Wait modes. The only low-power mode it supports is Standby.

41.12 Pad keeping

Pad-keeping allows you to retain the state of the pads while the MCU is in the Standby mode.

41.12.1 Pad keeping on Run domain pins

The process of entering Standby mode ensures that the chip maintains the state of the pads until it wakes-up and re-configures them by software. Software Standby mode entry sequence specifies that you must write 0 to DCM.DCMRWF1[STANDBY_IO_CONFIG] before configuring I/O pad keeping. You could consider

DCM.DCMRWF1[STANDBY_IO_CONFIG] field as a global enable for all pad keeping purposes during Standby mode. If you are unable to write to this field as described, pad keeping works as explained in this chapter, during Standby mode.

After the chip exits Standby mode, you must first re-configure your pads, and then, write 1 to DCM.DCMRWF1[STANDBY_IO_CONFIG] field (see "Chip specific register descriptions" in the DCM chapter). Writing 1 to this field disables pad keeping.

41.12.2 Pad keeping on Standby domain pins

See Table 250 for the Standby domain pins (all the rest are Run domain pins).

The Standby domain pads can have pad keeping enabled or disabled based on pad availability in Standby mode. Writing to SIUL2.MSCR*n*[PKE] field configures Standby mode pad keeping on a selected I/O.

Ensure that DCM.DCMRWF1[STANDBY_IO_CONFIG] = 0 before Standby mode entry for pad keeping on Standby domain pads. Write 0 to the field in case its value is not 0 already.

If a pad is not required during Standby mode, the corresponding MSCR*n*[PKE] field in SIUL2 must be 0.

41.12.3 Pad keeping configuration procedure

This procedure specifies how to enable an I/O for pad keeping:

1. Configure SIUL2.MSCR*n* register to control the pad state prior to Standby mode entry (for example, writing 0 to SIUL2.MSCR*n*[OBE], MSCR*n*[IBE], and MSCR[PUE] fields tristates the corresponding I/O).
2. Configure SIUL2.MSCR*n*[PKE] field as needed for an I/O pad keeping state during Standby mode.
3. Write 0 to DCM.DCMRWF1[STANDBY_IO_CONFIG].

   The application core executes WFI, and Standby mode sequence starts.
4. Write 1 to DCM.DCMRWF1[STANDBY_IO_CONFIG] field on Standby mode exit to disable pad keeping.

If you write 1 to DCM.DCMRWF1[STANDBY_IO_CONFIG] field before entering Standby mode, the isolation removal hardware removes pad keeping on Standby mode exit. This (writing 1 to DCM.DCMRWF1[STANDBY_IO_CONFIG] field before Standby mode entry) is useful in case of low-power debug because enabling pad keeping does not allow low-power debug protocol to work properly (because the TDO pad is padkept). For low-power debug, you must write 1 to DCM.DCMRWF1[STANDBY_IO_CONFIG] field prior to Standby mode entry.

In case of Standby mode exit by reset, the pad keeping of the reset pin is removed when the chip is reset on Standby mode wake up. See the "GPIO padkeeping enable" signal in Figure 183. The signal corresponds to wake-up via reset event case.

41.12.4 Pad keeping waveforms

41.12.4.1 Pad keeping when the chip wakes up from Standby mode via an interrupt wake-up event

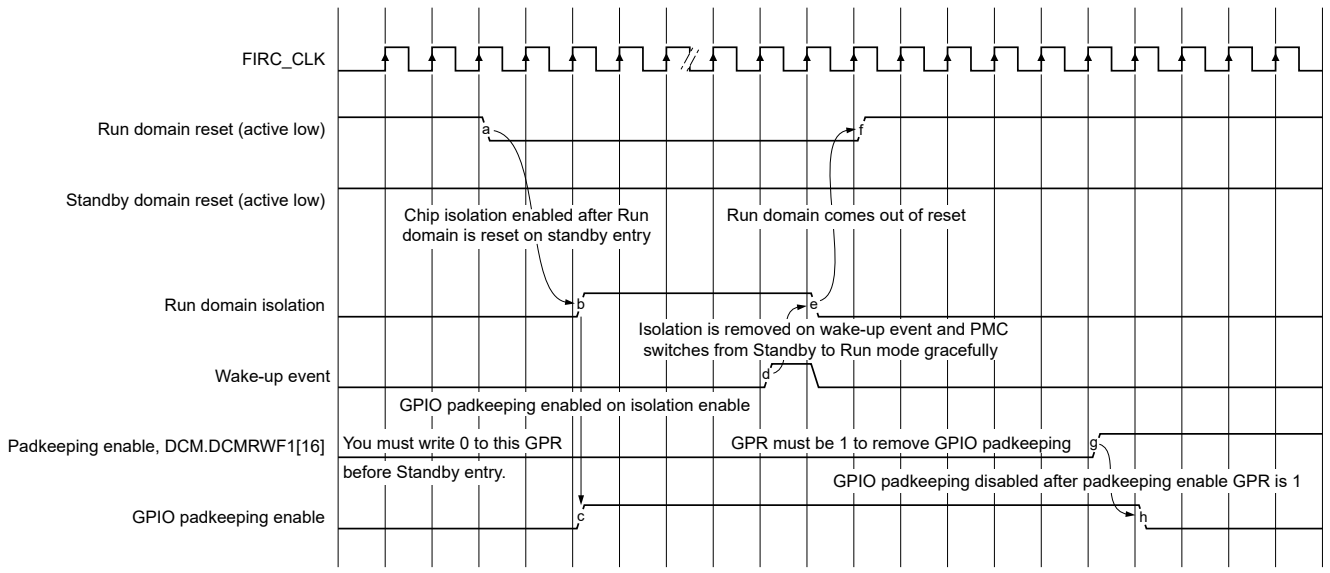

Figure 182. Pad keeping when the chip wakes up from Standby mode via an interrupt event

41.12.4.2 Pad keeping when the chip wakes up from Standby mode via reset

If the chip exits Standby mode via reset, the reset pad keeping is removed when the chip resets after Standby-mode wake-up. See the figure's "GPIO padkeeping enable" waveform corresponding to wake-up via a reset event.

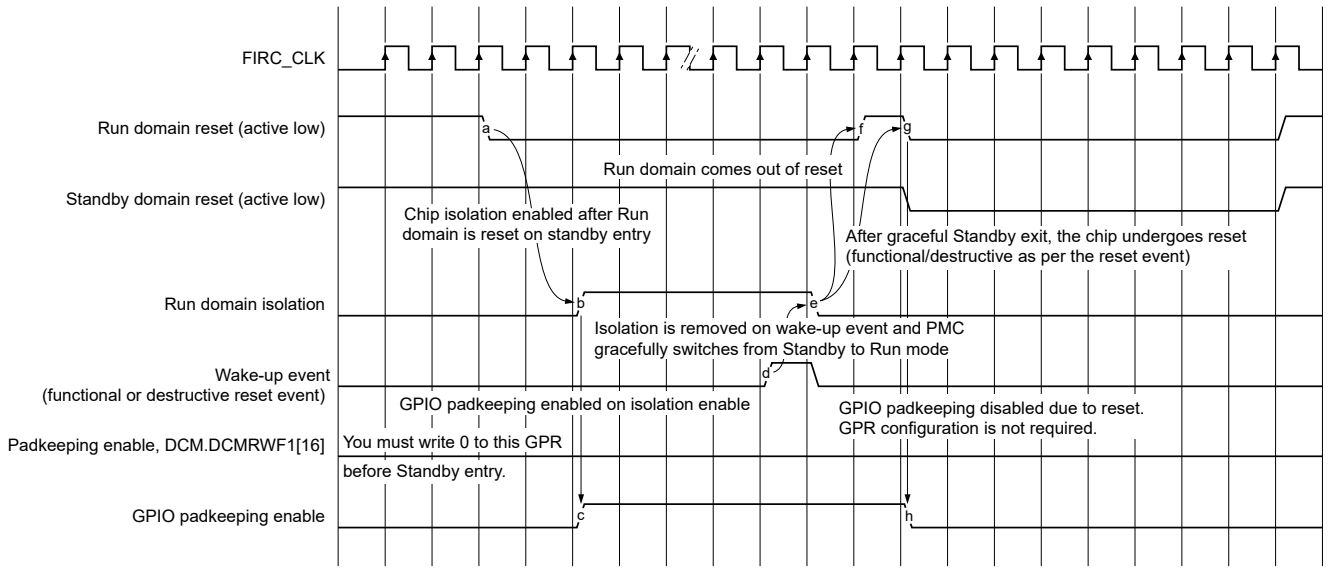

Figure 183. Pad keeping when the chip wakes up from Standby mode via reset

41.12.5 SIUL2's fields for actively-driven pins in Standby mode

If you use a WKPU pin as a wake-up input, perform these operations on SIUL2's fields:

1. Write 1 to SIUL2.MSCR*x*[IBE].

2. Program SIUL2.MSCR*x*[PUE] and SIUL2.MSCR*x*[PUS] according to the use case.
3. Write 0 to SIUL2.MSCR*x*[PKE].

For the GPIO pins that are driven to high impedance during Standby mode:

1. Write 0 to DCM.DCMRWF1[STANDBY_IO_CONFIG] field.
2. Write 0 to SIUL2.MSCR*x*[SSS] field (GPIO mode).
3. Write 0 to SIUL2.MSCR*x*[IBE] and SIUL2.MSCR*x*[OBE] fields.

Some of the pins are, by default, actively driven in Standby mode. If these pins retain a static value throughout the mode, program the corresponding SIUL2.MSCR*x*[PKE] bits individually.

This table shows the list of pins available in Standby mode along with the functions they perform.

Table 250. Active pins in Standby mode

Pin[1]	Function

41.13 Glossary

Application core Core apart from the main core

Boot regulator The on chip 1.1 V regulator that is active during startup and entry and exit from Standby mode

FSM Finite state machine

FPM Full-power mode (Run mode)—uses the last-mile regulator and 1.5 V source to generate the 1.1 V core logic supply during a full-power operation (V11_RUN)

LPM Low-power mode (Standby mode)—uses the low-power regulator to generate the 1.1 V core logic supply during low-power operation (V11_STANDBY)

LVR	Low voltage reset
Main core	Core initiating the chip Standby mode request (for example, the core corresponding to the "core index" in MC_ME's MAIN_COREID register)
Pad keeping	Maintains I/O pad configuration during Standby mode, if enabled
V11_STANDBY	Core logic and clock sources, low-voltage supply to Standby domain
V11_RUN	Low-voltage supply to Run domain
V15	High-current input for core or logic supply from either an external BJT or from direct 1.5 V external supply
V25	Flash memory, FXOSC, and PLLDIG high-voltage supply
VDDA_ADC	ADC supply voltage
VREFH	ADC high-voltage reference supply
VREFL	ADC low-voltage reference supply
VSS	Core logic ground supply
VDD_HV_A	Main I/O voltage supply (5 V or 3.3 V)
VDD_HV_B	Other I/O domain voltage supply (5 V or 3.3 V)
VRC_CTRL	PMC voltage regulator control output using the BJT option to generate a 1.5 V supply
WFI	Wait for interrupt software instruction

Chapter 42
Power Management Controller (PMC for S32K34x, S32K322, S32K324, and S32K314)

42.1 Introduction

PMC is the power management controller for the S32K3 family of microcontrollers. It provides multiple power options to allow you to optimize power consumption for the level of functionality needed. It includes internal voltage regulators, POR, and the integrated low/high voltage detect system with reset (brown-out) capability. The voltage regulator requires a 3.3 V or 5 V input to generate all the required secondary supplies.

42.2 Features

PMC includes the following features:

- Combination of internal and external voltage regulator options, offering RUN and Standby modes
- Active POR providing brown-out detect
- LVR for all system-relevant power domains
- LVD and HVD as indication for software

42.3 Modes of operation

PMC provides two basic modes of operation for the voltage regulators and monitors:

- FPM, which is used on chip-level in RUN modes: For high-current consumption
- LPM, which is used on chip-level for Standby modes: For low-current consumption

42.4 Block diagram

The following figure shows the block diagram for this module.

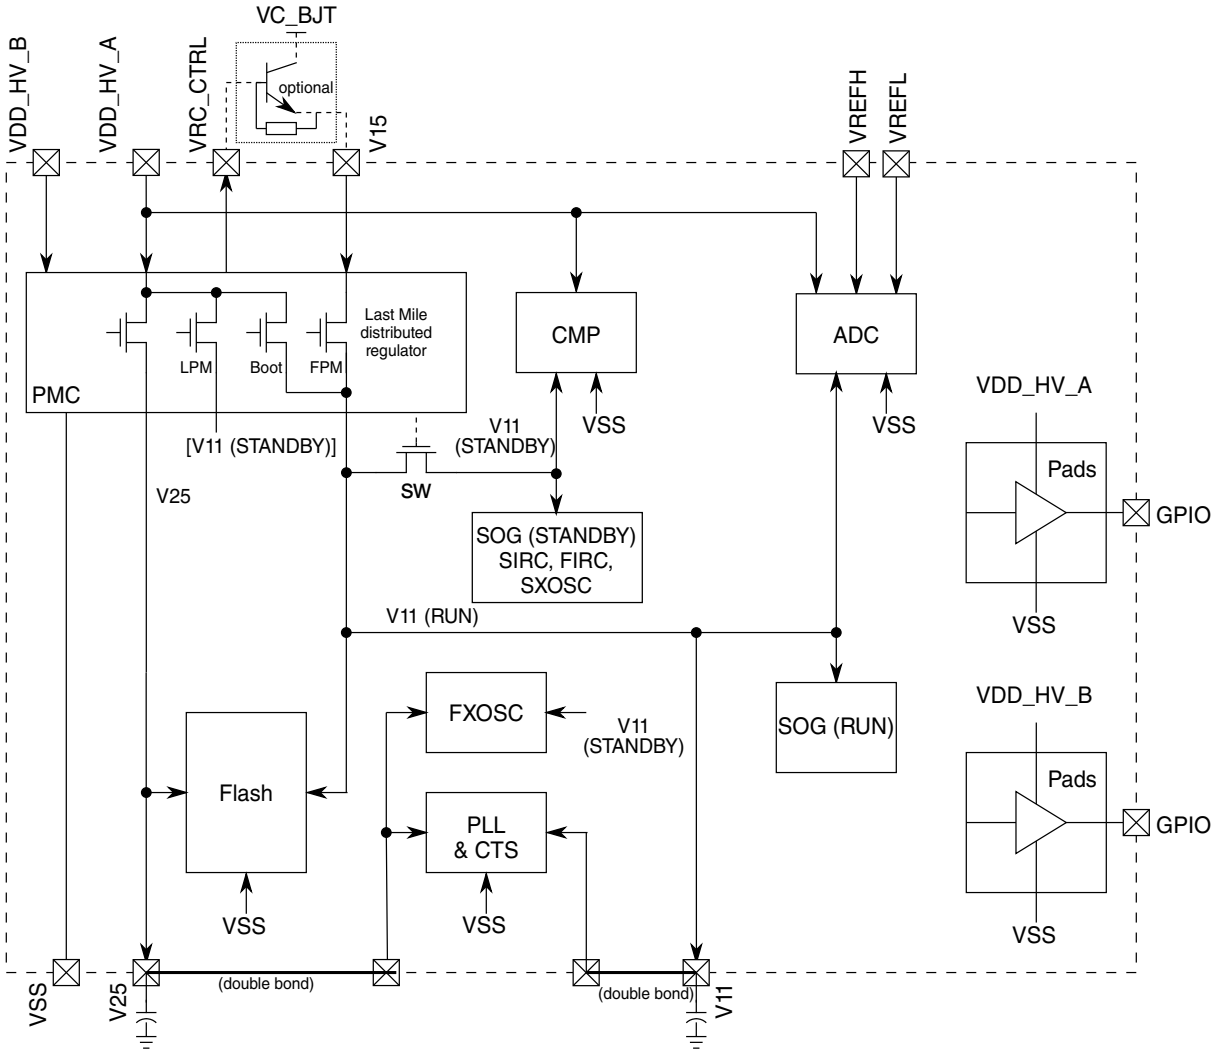

Figure 184. PMC block diagram

42.5 Signals

This table describes the PMC module signals.

Table 251. Signal Description

Signal	I/O	Description
VDD_HV_A	Supply input	This is the primary high-voltage supply input to PMC. VDD_HV_A is used for the PMC internal precision references. After the VDD_HV_A domain is powered up, it must be kept powered at all times of operation (FPM and LPM).
VDD_HV_B[1]	Supply input	This is the secondary high-voltage supply input supervised by the PMC. After the VDD_HV_B domain is powered up, it must be kept powered at all times of operation (FPM and LPM).

Table continues on the next page...

Table 251. Signal Description (continued)

Signal	I/O	Description
V25	Supply output	V25 power supply domain is driven by a fully integrated low-dropout linear voltage regulator. It supplies the Flash memory and (via a double bond) the clock modules.
V15[1]	Supply input	This is the high-current input for core/logic supply that can be fed by an external BJT or another source.
VRC_CTRL	Output	VRC_CTRL connects to the base of external BJT, if this option is used to generate V15.
V11	Supply output	V11 is the core/logic supply. It is driven by a fully integrated low-dropout linear voltage regulator.
VSS	Ground	VSS must be grounded. All VSS Pins need to be externally connected to the same ground node.

1. VDD_HV_B and V15 not present in S32K312 and S32K311.

42.6 Functional description

The following sections describe functional details of the PMC.

42.6.1 Reset

The POR and all LVRs are combined into one single MCU POR.

After an MCU POR event, it can be determined which power domain caused it, by reading in the PMC_LVSC register, the POR flag, and LVR flags.

After an initial power ramp up of the MCU in the PMC_LVSC register, the POR flag and the LVR flags are all set to 1. The Go/Nogo flags have an arbitrary value.

NOTE

After an initial power ramp up, all flags in the LVSC register must be cleared (by writing 0xFFFFFFFF to the LVSC register).

Because the flags are sticky bits, it is required to clear them before usage. So, in case of an unexpected MCU POR, the source of the problem can be tracked and debugged by reading the flags in the LVSC register.

42.6.2 Interrupts

PMC includes two interrupt sources:

- HVD interrupt: It combines all HVD monitors into one interrupt source. Interrupt enable is the HVDIE field in the CONFIG register. See the PMC Configuration Register (CONFIG) and Low Voltage Status and Control Register (LVSC) registers for details.
- LVD interrupt: It combines the LVD15 and LVD5A monitors into one interrupt source. Interrupt enable is the LVDIE field in the CONFIG register. See the CONFIG and LVSC registers for details.

42.7 PMC register descriptions

42.7.1 PMC memory map

This section includes the PMC module memory map and detailed descriptions for all the registers.

DEFAULT_NICKNAME base address: 0h

Offset	Register	Width (In bits)	Access	Reset value
0h	Low Voltage Status and Control Register (LVSC)	32	RW	See section
4h	PMC Configuration Register (CONFIG)	32	RW	See section
Ch	Version ID register (VERID)	32	R	0200_0001h

42.7.2 Low Voltage Status and Control Register (LVSC)

Offset

Register	Offset
LVSC	0h

Function

This register contains status and control bits to support the low-voltage reset and low- or high-voltage detect function. When the PMC is in LPM, the low- or high-voltage detect systems are disabled.

NOTE

For all flags that are not affected by reset (POR flag, all LVR flags, all GNG flags), in case a reset occurs at the same time while trying to clear the flags (by writing 1), the flag value is not defined appropriately. In this case, you need to clear the flag again after exit from reset.

Fields

Field	Function
31 PORF	POR flag Indicates that a power-on reset event has occurred. Writing 1 to this field clears it, and other reset sources have no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No power-on reset event has occurred 1b - Power-on reset event has occurred
30-26 —	Reserved
25 GNG11OSCF	Go/NoGo detect flag on Osc part of V11 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V11 domain in FPM. This applies to only that part of the domain which supplies the 1.1V clocking modules (for example, PLL). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred
24 GNG25OSCF	GO/NoGo detect flag on Osc part of V25 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V25 domain in FPM. This applies to only that part of the domain which supplies the 2.5V clocking modules (for example, XOSC and IRC). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred
23 LVR11LPF	LVR11LP flag on V11 domain Indicates that a low-voltage reset event has occurred on the 1.1V V11 power domain (FPM or LPM). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
22 LVR11F	LVR11 flag on V11 domain in FPM Indicates that a low-voltage reset event has occurred on the 1.1V V11 power domain in the FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
21 LVR25LPF	LVR25LP flag on V25 domain Indicates that a low-voltage reset event has occurred on the V25 power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
20 LVR25F	LVR25 flag on V25 domain in FPM Indicates that a low-voltage reset event has occurred on the V25 power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
19 LVRBLPF	LVRBLP flag on VDD_HV_B domain Indicates that a low-voltage reset event has occurred on the VDD_HV_B power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
18 LVRBF	LVRB flag on VDD_HV_B domain in FPM Indicates that a low-voltage reset event has occurred on the VDD_HV_B power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
17 LVRALPF	LVRALP flag on VDD_HV_A domain Indicates that a low-voltage reset event has occurred on the VDD_HV_A power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
16 LVRAF	LVRA flag on VDD_HV_A domain in FPM Indicates that a low-voltage reset event has occurred on the VDD_HV_A power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
15-14 —	Reserved
13 LVD15S	LVD15 status on V15 domain in FPM Shows the status of the 1.5V low-voltage detect, LVD15, on the V15 power domain. This monitor indicates when the V15 voltage level generated from external is on target. This feature is available only in FPM and disabled in LPM. After a reset or wakeup from LPM, the software should clear the LVD15F flag and check the status bit LVD15S to determine voltage level on V15 supply. 0b - Voltage on V15 is above low-voltage detect threshold or LPM. 1b - Voltage on V15 is below low-voltage detect threshold and FPM.
12 LVD5AS	LVD5A status on VDD_HV_A domain in FPM Shows the status of the 5V low-voltage detect, LVD5A, on the VDD_HV_A power domain. This monitor indicates if the voltage is below a certain threshold, which is set slightly below 4.5V (see Datasheet for

Table continues on the next page...

Table continued from the previous page...

Field	Function
	exact value). The feature is only available in FPM and disabled in LPM. After a reset or wakeup from LPM, the software should clear the LVD5AF flag and check the status bit LVD5AS to determine voltage level on VDD_HV_A supply. 0b - Voltage on VDD_HV_A is above low-voltage detect threshold 1b - Voltage on VDD_HV_A is below low-voltage detect threshold
11 HVD11S	HVD11 status on V11 domain in FPM Shows the status of the high-voltage detect, HVD11, on the V11 power domain. This feature is only available in FPM and disabled in LPM. 0b - Voltage on V11 is below high-voltage detect threshold or LPM. 1b - Voltage on V11 is above high-voltage detect threshold and FPM.
10 HVD25S	HVD25 status on V25 domain in FPM Shows the status of the high-voltage detect, HVD25, on the V25 power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on V25 is below high-voltage detect threshold or LPM. 1b - Voltage on V25 is above high-voltage detect threshold and FPM.
9 HVDBS	HVDB status on VDD_HV_B domain in FPM Shows the status of the high-voltage detect, HVDB, on the VDD_HV_B power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on VDD_HV_B is below high-voltage detect threshold or LPM. 1b - Voltage on VDD_HV_B is above high-voltage detect threshold and FPM.
8 HVDAS	HVDA status on VDD_HV_A domain in FPM Shows the status of the high-voltage detect HVDA on the VDD_HV_A power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on VDD_HV_A is below high-voltage detect threshold or LPM. 1b - Voltage on VDD_HV_A is above high-voltage detect threshold and FPM.
7-6 —	Reserved
5 LVD15F	LVD15 flag on V15 domain in FPM PMC writes 1 to the LVD15F field when the LVD15S status field changes. To clear LVD15F, write 1 to it. If enabled, LVD15F causes an interrupt request. 0b - LVD15S has not changed. 1b - LVD15S has changed.
4	LVD5A flag on VDD_HV_A domain in FPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
LVD5AF	PMC writes 1 to this field when LVD5AS status field changes. To clear LVD5AF, write 1 to it. If enabled, LVD5AF causes an interrupt request. 0b - LVD5AS has not changed. 1b - LVD5AS has changed.
3 HVD11F	HVD11 flag on V11 domain in FPM PMC writes 1 to this field when the HVD11S status field changes. To clear HVD11F, write 1 to it. If enabled, HVD11F causes an interrupt request. 0b - HVD11S has not changed. 1b - HVD11S has changed.
2 HVD25F	HVD25 flag on V25 domain in FPM PMC writes 1 to the HVD25F field when HVD25S status field changes. To clear HVD25F, write 1 to it. If enabled, HVD25F causes an interrupt request. 0b - HVD25S has not changed. 1b - HVD25S has changed.
1 HVDBF	HVDB flag on VDD_HV_B domain in FPM PMC writes 1 to the HVDBF field when HVDBS status field changes. To clear HVDBF, write 1 to it. If enabled, HVDBF causes an interrupt request. 0b - HVDBS has not changed. 1b - HVDBS has changed.
0 HVDAF	HVDA flag on VDD_HV_A domain in FPM PMC writes 1 to the HVDAF field when HVDAS status field changes. To clear HVDAF, write 1 to it. If enabled, HVDAF causes an interrupt request. 0b - HVDAS has not changed. 1b - HVDAS has changed.

42.7.3 PMC Configuration Register (CONFIG)

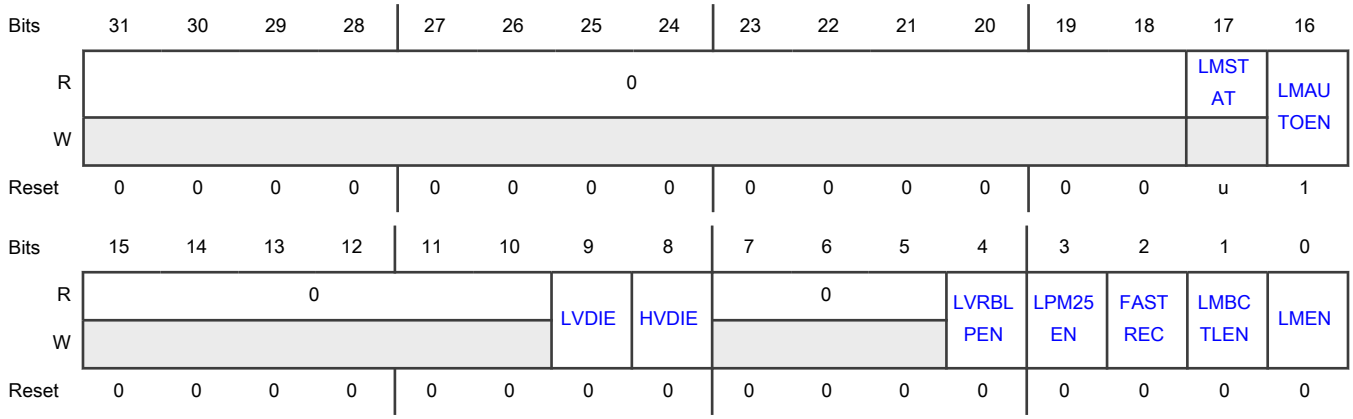
Offset

Register	Offset
CONFIG	4h

Function

If the Last Mile Regulator option is not available on your device (Version ID register (VERID) register: LMFEAT=0), then the bits LMEN, LMBCTLEN, LMAUTOEN and LMSTAT fields can not be written and read always 0.

Diagram



Fields

Field	Function
31-18 —	Reserved
17 LMSTAT	Last Mile regulator status bit This bits reflects the current status of the Last Mile regulator. This information is required as when auto turn over feature is enabled (LMAUTOEN=1) the PMC will switch automatically between Boot regulator and Last Mile regulator depending on the V15 status (LVD15S). 0b - Last Mile Regulator is off 1b - Last Mile Regulator is on
16 LMAUTOEN	Last Mile regulator auto turn over bit Enables to turn over automatically from Boot Regulator Mode to Last Mile regulator mode and vice versa depending on the V15 voltage status (LVD15S). As long as LMEN=0 software must make sure that the system clock is on FIRC clock or slower. To use higher clock speed software must set LMEN=1. 0b - Auto turnover disabled 1b - Auto turnover enabled
15-10 —	Reserved
9 LVDIE	Low voltage detect interrupt enable Enables hardware interrupt requests if any of the following flags is set: LVD5AF, LVD15F. LVD interrupt must be disabled before going into LPM. 0b - LVD hardware interrupt is disabled (use polling). 1b - Request an LVD hardware interrupt when LVDA5F=1 or LVD15F=1.
8 HVDIE	High voltage detect interrupt enable

Table continued from the previous page...

Field	Function
	Enables hardware interrupt requests if any of the following flags is set: HVDAF, HVDBF, HVD25F, HVD11F. 0b - HVD hardware interrupt is disabled (use polling). 1b - Request an HVD hardware interrupt when HVDAF=1, HVDBF=1, HVD25F=1, or HVD11F=1.
7-5 —	Reserved
4 LVRBLPEN	LVRBLP enable bit during LPM Controls whether the low-voltage reset detection (LVRBLP) on the VDD_HV_B power domain is active or inactive in LPM 0b - Low-voltage reset detection is disabled in LPM. 1b - Low-voltage reset detection is enabled in LPM.
3 LPM25EN	V25 domain enable bit during LPM Controls whether the V25 regulator and low-voltage reset detection (LVR25LP) are active or inactive in LPM 0b - V25 regulator and LVR25LP are disabled in LPM. 1b - V25 regulator and LVR25LP are enabled in LPM.
2 FASTREC	Fast recovery from LPM enable bit Controls the recovery time from LPM to FPM. At recovery from LPM, all the tank capacitors from the secondary supplies have to be recharged. This causes a high-current demand, which might not be met by the supply driving the VDD_HV_A primary domain. When selecting the fast recovery time, the current for recharging is approximately three times higher than that for FASTREC=0. The application must determine from the drive capability of the external VDD_HV_A regulator, the size of tank caps on the secondary supply pins and the selected recovery time if this is sufficient to start up from LPM in time. 0b - Normal recovery time from LPM 1b - Fast recovery time from LPM
1 LMBCTLEN	Last Mile regulator base control enable bit This field must be set to 1 if external BJT between VDD_HV_A and V15 is used on the PCB. The base of this BJT must be connected to the VRC_CTRL pin and is controlled by the PMC to regulate a voltage of 1.5V on V15 pin. After setting LMBCTLEN=1 the software has to wait for 15us (FASTREC=1) respectively 50us (FASTREC=0) before polling LVD15S=0 and then setting LMEN=1. This respects the softstart time of the V15 regulator. If LMAUTOEN=1 then LMBCTLEN can be left enabled when going into LPM, the hardware will turn the regulator off and back on automatically after recovery from LPM. 0b - External BCTL regulator for V15 disabled 1b - External BCTL regulator for V15 enabled
0 LMEN	Last Mile regulator enable bit

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables the Last Mile regulator, which regulates an external 1.5V voltage on V15 down to the core and logic supply (V11 power domain), which is typically 1.1V. Setting LMEN=1 hands over the V11 voltage generation from the Boot regulator to the Last Mile regulator. The software must ensure that before enabling the Last Mile regulator, the voltage on V15 is sufficiently high as indicated by the LVD15S status field (LVD15S=0). To use external BJT between VDD_HV_A and V15, the LMBCTLEN field must be set before the LMEN field, and the software must wait until 1.5V is up (LVD15S=0). If LMAUTOEN=0 then to disable the Last Mile regulator, LMEN and LMBCTLEN must be cleared simultaneously (single register write). The software must disable (LMEN=0) the Last Mile regulator before going into LPM. After setting LMEN=1, software must wait a minimum time of 1.5us before changing clock rate. 0b - Last Mile regulator is disabled. 1b - Last Mile regulator is enabled.

42.7.4 Version ID register (VERID)

Offset

Register	Offset
VERID	Ch

Function

This register returns the major and minor version numbers of hardware implementation.

Chapter 43
Power Management Controller (PMC for S32K310, S32K311 and S32K312)

43.1 Introduction

PMC provides multiple power options to allow you to optimize power consumption for the appropriate level of functionality. It includes:

- Internal voltage regulators
- POR
- Integrated low and high voltage detection system with reset (brownout) capability

The voltage regulator requires a 3.3 V or 5 V input to generate all the required secondary supplies.

43.2 Features

- A combination of internal and external voltage regulator options, offering Run and Standby modes
- Active POR, providing brownout detect
- LVR for all system-relevant power domains
- Software-readable Low Voltage Status and Control register that contains flags that indicate low- or high-voltage conditions

43.3 Modes of operation

PMC provides two basic modes of operation for voltage regulators and monitors:

- FPM supports chip run modes that have high current consumption.
- LPM supports chip standby modes that have low current consumption.

43.4 Block diagram

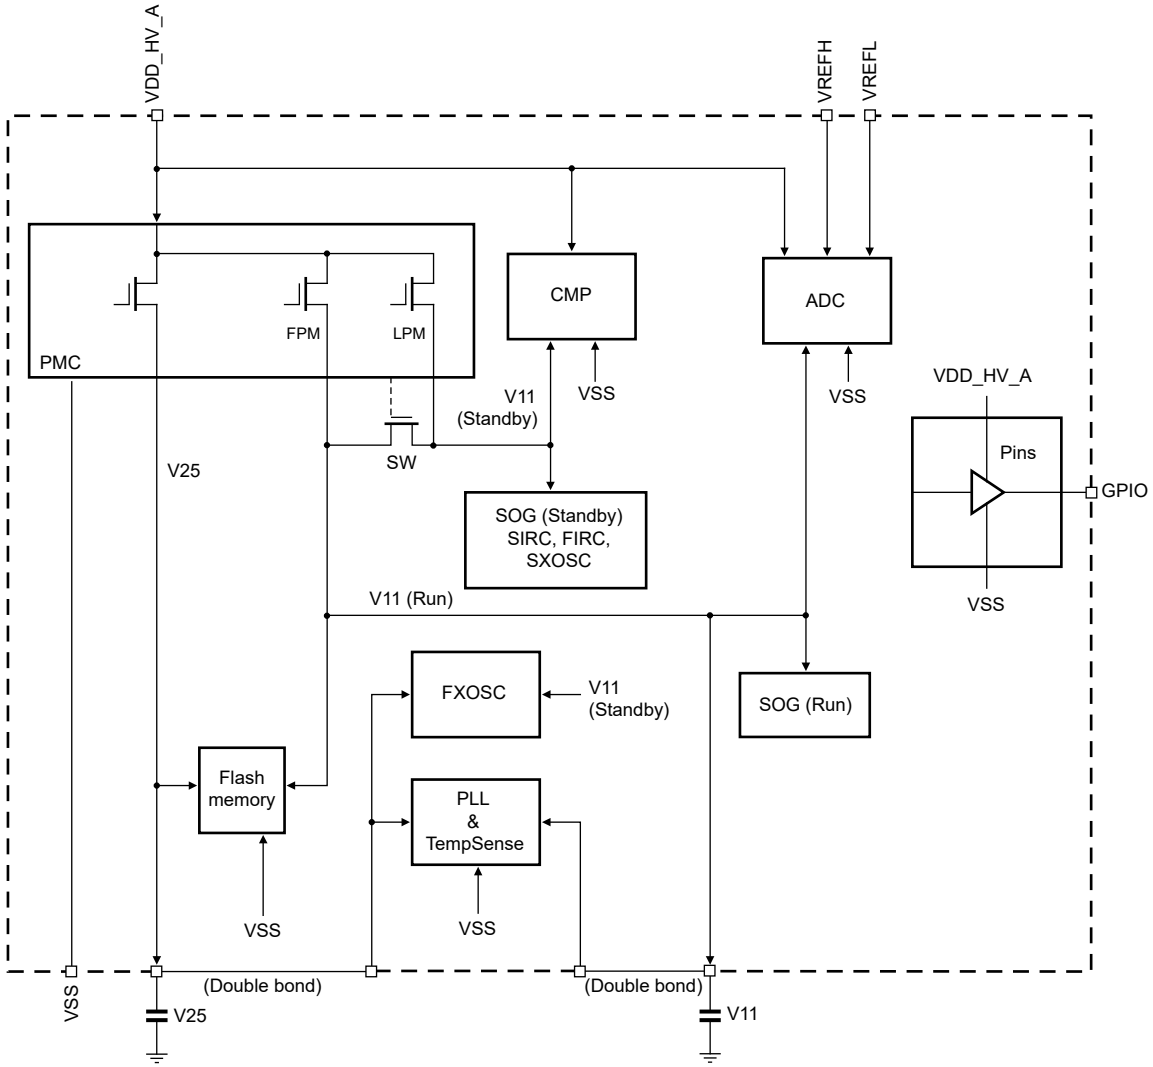

Figure 185. Block diagram

43.5 Signals

Table 252. Signals

Signal	Type	Description
VDD_HV_A	Supply input	The primary high-voltage supply input to PMC. VDD_HV_A is used for the PMC internal precision references. After the VDD_HV_A power domain is powered up, it must always be kept powered for both FPM and LPM.
V25	Supply output	A fully integrated low-dropout linear voltage regulator drives the V25 power supply domain. V25 supplies the flash memory and (via a double bond) the clock modules.

Table continues on the next page...

Table 252. Signals (continued)

Signal	Type	Description
V11	Supply output	V11 is the core and logic supply. A fully integrated low-dropout linear voltage regulator drives V11.
VSS	Ground	VSS must be grounded. You must connect all VSS pins externally to the same ground node.

43.6 Functional description

43.6.1 Reset

The POR and all LVRs combine into one single chip POR.

After a chip POR event, you can determine which power domain caused it by reading the PORF and LVR*x* flags in Low Voltage Status And Control (LVSC).

After an initial power ramp-up of the chip in LVSC, PMC sets the POR and LVR*x* flags. The go/no go flags have an arbitrary value.

NOTE

After an initial power ramp-up, you must clear all flags in LVSC by writing FFFF_FFFFh to that register.

Because the flags are sticky bits, you must clear them before using them. That way, if an unexpected chip POR occurs you can track and debug the source of the problem by reading the flags in LVSC.

43.6.2 Interrupts

PMC includes two interrupt sources:

- HVD interrupt: Combines all HVD monitors into one interrupt source. CONFIG[HVDIE] enables this interrupt. See PMC Configuration (CONFIG) and Low Voltage Status And Control (LVSC) for details.
- LVD interrupt: The LVD5A monitor is the only interrupt source. CONFIG[LVDIE] enables this interrupt. See PMC Configuration (CONFIG) and Low Voltage Status And Control (LVSC) for details.

0h	Low Voltage Status And Control (LVSC)	32	RW	See section
4h	PMC Configuration (CONFIG)	32	RW	0000_0000h
Ch	Version ID (VERID)	32	R	0300_0000h

43.7.2 Low Voltage Status And Control (LVSC)

Offset

Register	Offset
LVSC	0h

Function

Contains status and control fields that support the low-voltage reset and low- or high-voltage detect functions. When PMC is in LPM, the low- or high-voltage detect systems are disabled.

NOTE

For all flags that are not affected by reset (POR flag, all LVR flags, all GNG flags), if a reset occurs while trying to clear the flags (by writing 1), the flag value is not defined appropriately. In this case, you must clear the flag again after exiting from reset.

12	LVD5A Status On VDD_HV_A Power Domain In FPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
LVD5AS	Indicates whether the voltage on VDD_HV_A is above or below the low-voltage detect threshold. This monitor reflects the status of the 5 V low-voltage detect, LVD5A, and indicates if the voltage is below a certain threshold, which is set slightly below 4.5 V (see the chip data sheet for the exact value). The feature is only available in FPM and is disabled in LPM. After a reset or wake-up from LPM, you must clear the LVD5AF flag and check LVD5AS to determine the voltage level on the VDD_HV_A supply. 0b - Above 1b - Below
11 HVD11S	HVD11 Status On V11 Power Domain In FPM Indicates whether the voltage on V11 is above or below the high-voltage detect threshold. This field reflects the status of the high-voltage detect, HVD11, on the V11 power domain. This feature is only available in FPM and is disabled in LPM. 0b - Voltage is below threshold or chip is in LPM 1b - Voltage is above threshold and chip is in FPM
10 HVD25S	HVD25 Status On V25 Power Domain In FPM Indicates whether the voltage on V25 is above or below the high-voltage detect threshold. This field reflects the status of the high-voltage detect, HVD25, on the V25 power domain. The feature is only available in FPM and is disabled in LPM. 0b - Voltage is below threshold or chip is in LPM 1b - Voltage is above threshold and chip is in FPM
9 —	Reserved
8 HVDAS	HVDA Status On VDD_HV_A Power Domain In FPM Indicates whether the voltage on VDD_HV_A is above or below the high-voltage detect threshold. This field reflects the status of the high-voltage detect, HVDA, on the V25 power domain. The feature is only available in FPM and is disabled in LPM. 0b - Voltage is below threshold or chip is in LPM 1b - Voltage is above threshold and chip is in FPM
7-5 —	Reserved
4 LVD5AF	LVD5A Flag On VDD_HV_A Power Domain In FPM Indicates whether LVD5AS has changed. When LVD5AS changes, PMC changes LVD5AF to 1. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Did not change 1b - Changed When writing 0b - No effect 1b - Clear the flag
3 HVD11F	HVD11 Flag On V11 Power Domain In FPM Indicates whether HVD11S has changed. When HVD11S changes, PMC changes HVD11F to 1. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not change 1b - Changed When writing 0b - No effect 1b - Clear the flag
2 HVD25F	HVD25 Flag On V25 Power Domain In FPM Indicates whether HVD25S has changed. When HVD25S changes, PMC changes HVD25F to 1. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not change 1b - Changed When writing 0b - No effect 1b - Clear the flag
1 —	Reserved
0 HVDAF	HVDA Flag On VDD_HV_A Power Domain In FPM Indicates whether HVDAS has changed. When HVDAS changes, PMC changes HVDAF to 1. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Chapter 44
Power Management Controller (PMC for S32K358, S32K328, S32K338, and S32K348)

44.1 Introduction

PMC is the power management controller for the S32K3 family of microcontrollers. It provides multiple power options to allow you to optimize power consumption for the level of functionality needed. It includes internal voltage regulators, POR, and the integrated low/high voltage detect system with reset (brown-out) capability. The voltage regulator requires a 3.3 V or 5 V input to generate all the required secondary supplies.

44.2 Features

PMC includes the following features:

- Combination of internal and external voltage regulator options, offering RUN and Standby modes
- Active POR providing brown-out detect
- LVR for all system-relevant power domains
- LVD and HVD as indication for software

44.3 Modes of operation

PMC provides two basic modes of operation for the voltage regulators and monitors:

- FPM, which is used on chip-level in RUN modes: For high-current consumption
- LPM, which is used on chip-level for Standby modes: For low-current consumption

44.4 Block diagram

The following figure shows the block diagram for this module.

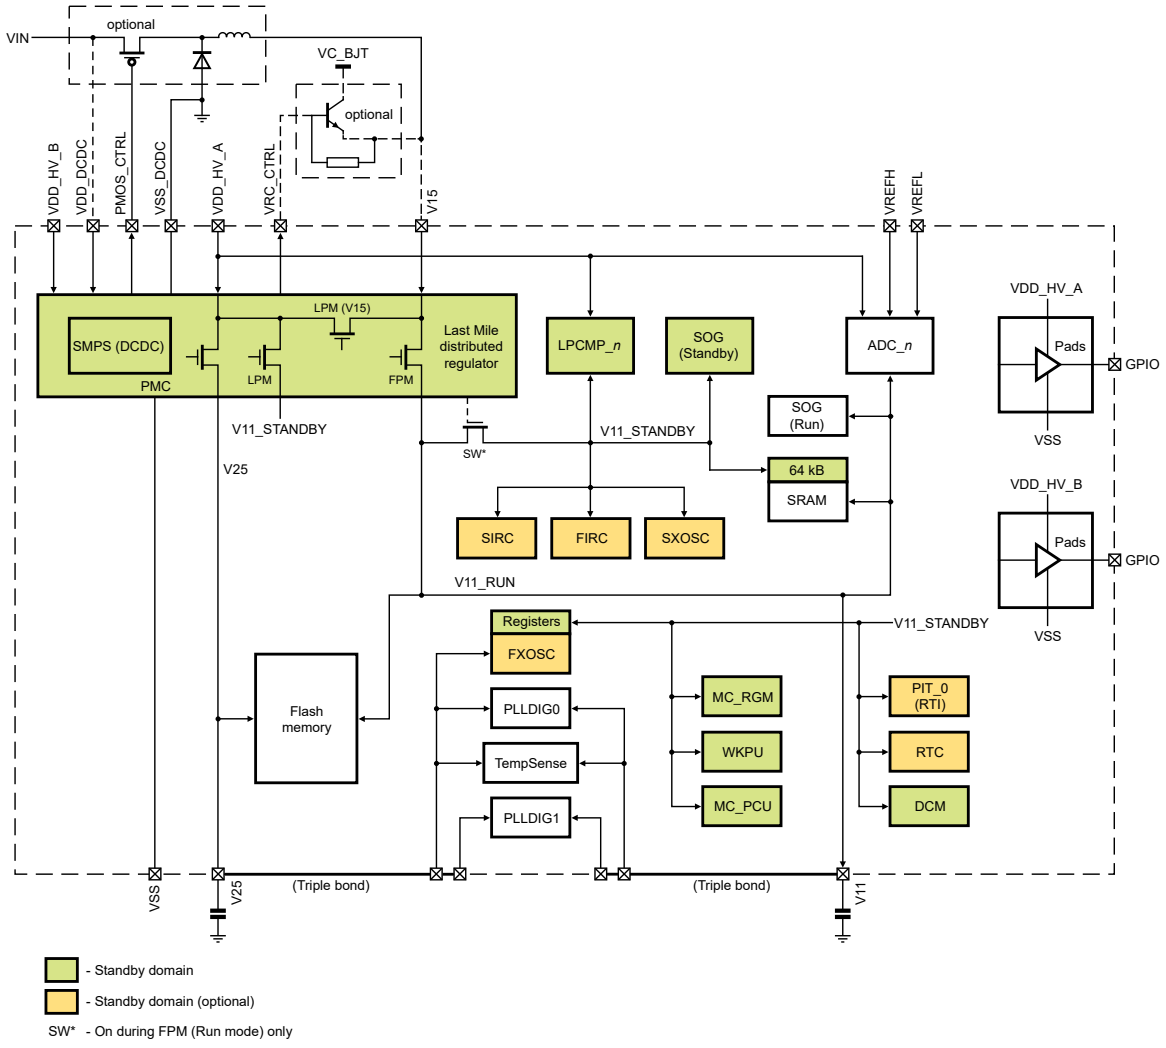

Figure 186. PMC block diagram

44.5 Signals

This table describes the PMC module signals.

Table 253. Signal Description

Signal	I/O	Description
VDD_HV_A	Supply input	This is the primary high-voltage supply input to PMC. VDD_HV_A is used for the PMC internal precision references. After the VDD_HV_A domain is powered up, it must be kept powered at all times of operation (FPM and LPM).
VDD_HV_B	Supply input	This is the secondary high-voltage supply input supervised by the PMC. After the VDD_HV_B domain is powered up, it must be kept powered at all times of operation (FPM and LPM).

Table continues on the next page...

Table 253. Signal Description (continued)

Signal	I/O	Description
V25	Supply output	V25 power supply domain is driven by a fully integrated low-dropout linear voltage regulator. It supplies the Flash memory and (via a double bond) the clock modules.
V15	Supply input	This is the high-current input for core/logic supply that can be fed by an external BJT or the SMPS or an external source.
VRC_CTRL	Output	VRC_CTRL connects to the base of external BJT, if this option is used to generate V15.
V11	Supply output	V11 is the core/logic supply. It is driven by a fully integrated low-dropout linear voltage regulator.
VSS	Ground	VSS must be grounded. All VSS Pins need to be externally connected to the same ground node.
VDD_DCDC	Supply input	This is the power supply domain for the SMPS gate driver and must be shorted with the source voltage of the external power FET. An off-chip decoupling capacitor between VDD_DCDC and ground is required. See Datasheet for the recommended value. **NOTE** If SMPS (DCDC) mode is used and the PMC is in low power mode, it must be ensured that SMPS supply input VDD_DCDC is fully operational and loadable before wake-up from low power mode. Otherwise a low voltage reset might occur on wake-up.
VSS_DCDC	Ground	This is the power ground for the SMPS gate driver and must be shorted with the main ground node and the ground node of the external Schottky diode.
PMOS_CTRL	Output	This is the gate driver output for the external power FET for the SMPS regulator.

44.6 Functional description

The following sections describe functional details of the PMC.

44.6.1 Reset

The POR and all LVRs are combined into one single MCU POR.

After an MCU POR event, it can be determined which power domain caused it, by reading in the PMC_LVSC register, the POR flag, and LVR flags.

After an initial power ramp up of the MCU in the PMC_LVSC register, the POR flag and the LVR flags are all set to 1. The Go/Nogo flags have an arbitrary value.

NOTE

After an initial power ramp up, all flags in the LVSC register must be cleared (by writing 0xFFFFFFFF to the LVSC register).

Because the flags are sticky bits, it is required to clear them before usage. So, in case of an unexpected MCU POR, the source of the problem can be tracked and debugged by reading the flags in the LVSC register.

44.6.2 Interrupts

PMC includes two interrupt sources:

- HVD interrupt: It combines all HVD monitors into one interrupt source. Interrupt enable is the HVDIE field in the CONFIG register.
- LVD interrupt: This is the interrupt for the LVD5A monitor. Interrupt enable is the LVDIE field in the CONFIG register.

See the PMC Configuration Register (CONFIG) and Low Voltage Status and Control Register (LVSC) registers for details.

44.7 PMC register descriptions

44.7.1 PMC memory map

This section includes the PMC module memory map and detailed descriptions for all the registers.

PMC_S32K358 base address: 402E_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Low Voltage Status and Control Register (LVSC)	32	RW	See section
4h	PMC Configuration Register (CONFIG)	32	RW	0000_0083h
8h	SMPS Configuration Register (SMPSCONFIG)	32	RW	See section
Ch	Version ID register (VERID)	32	R	0400_0001h

44.7.2 Low Voltage Status and Control Register (LVSC)

Offset

Register	Offset
LVSC	0h

Function

This register contains status and control bits to support the low-voltage reset and low- or high-voltage detect function. When the PMC is in LPM, the low- or high-voltage detect systems are disabled.

NOTE

For all flags that are not affected by reset (POR flag, all LVR flags, all GNG flags), in case a reset occurs at the same time while trying to clear the flags (by writing 1), the flag value is not defined appropriately. In this case, you need to clear the flag again after exit from reset.

NOTE

For the GNG flags, in case a GNG event occurs at the same time as the GNG flag is read, the flag value might not be defined appropriately. In such case, you need to read the flag twice and consider the value only if it both read values match.

Fields

Field	Function
31 PORF	POR flag Indicates that a power-on reset event has occurred. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No power-on reset event has occurred 1b - Power-on reset event has occurred
30-28 —	Reserved
27 GNG11OSC2F	Go/NoGo detect flag on 2nd PLL part of V11 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V11 domain in FPM. This applies to only that part of the domain which supplies the 2nd PLL. Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred
26 GNG25OSC2F	GO/NoGo detect flag on 2nd PLL part of V25 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V25 domain in FPM. This applies to only that part of the domain which supplies the 2nd PLL. Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred
25 GNG11OSCF	Go/NoGo detect flag on Osc part of V11 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V11 domain in FPM. This applies to only that part of the domain which supplies the 1.1V clocking modules (e.g. PLL, IRC). Writing 1 to the field clears it, and other reset sources have no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No event has occurred 1b - NoGo event has occurred
24 GNG25OSCF	GO/NoGo detect flag on Osc part of V25 domain Indicates that the Go/NoGo sensor has detected a low voltage on the V25 domain in FPM. This applies to only that part of the domain which supplies the 2.5V clocking modules (e.g. PLL, XOSC and IRC). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No event has occurred 1b - NoGo event has occurred
23 LVR11LPF	LVR11LP flag on V11 domain Indicates that a low-voltage reset event has occurred on the 1.1V V11 power domain (FPM or LPM). Writing 1 to the field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
22 LVR11F	LVR11 flag on V11 domain in FPM Indicates that a low-voltage reset event has occurred on the 1.1V V11 power domain in the FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
21 LVR25LPF	LVR25LP flag on V25 domain Indicates that a low-voltage reset event has occurred on the V25 power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
20 LVR25F	LVR25 flag on V25 domain in FPM Indicates that a low-voltage reset event has occurred on the V25 power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
19 LVRBLPF	LVRBLP flag on VDD_HV_B domain Indicates that a low-voltage reset event has occurred on the VDD_HV_B power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred

Table continues on the next page...

Table continued from the previous page...

Field	Function
18 LVRBF	LVRB flag on VDD_HV_B domain in FPM Indicates that a low-voltage reset event has occurred on the VDD_HV_B power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
17 LVRALPF	LVRALP flag on VDD_HV_A domain Indicates that a low-voltage reset event has occurred on the VDD_HV_A power domain (FPM or LPM). Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
16 LVRAF	LVRA flag on VDD_HV_A domain in FPM Indicates that a low-voltage reset event has occurred on the VDD_HV_A power domain in FPM. Writing 1 to this field clears it, and other reset sources have no effect. 0b - No low-voltage reset event has occurred 1b - Low-voltage reset event has occurred
15 —	Reserved
14 HVD15S	HVD15 status on V15 domain in FPM Shows the status of the high-voltage detect, HVD15, on the V15 power domain. This feature is only available in FPM and disabled in LPM. 0b - Voltage on V15 is below high-voltage detect threshold or LPM. 1b - Voltage on V15 is above high-voltage detect threshold and FPM.
13 —	Reserved, ignore value Reserved, ignore value
12 LVD5AS	LVD5A status on VDD_HV_A domain in FPM Shows the status of the 5V low-voltage detect, LVD5A, on the VDD_HV_A power domain. This monitor indicates if the voltage is below a certain threshold, which is set slightly below 4.5V (see Datasheet for exact value). The feature is only available in FPM and disabled in LPM. After a reset or wakeup from LPM, the software should clear the LVD5AF flag and check the status bit LVD5AS to determine voltage level on VDD_HV_A supply. 0b - Voltage on VDD_HV_A is above low-voltage detect threshold 1b - Voltage on VDD_HV_A is below low-voltage detect threshold
11 HVD11S	HVD11 status on V11 domain in FPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Shows the status of the high-voltage detect, HVD11, on the V11 power domain. This feature is only available in FPM and disabled in LPM. 0b - Voltage on V11 is below high-voltage detect threshold or LPM. 1b - Voltage on V11 is above high-voltage detect threshold and FPM.
10 HVD25S	HVD25 status on V25 domain in FPM Shows the status of the high-voltage detect, HVD25, on the V25 power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on V25 is below high-voltage detect threshold or LPM. 1b - Voltage on V25 is above high-voltage detect threshold and FPM.
9 HVDBS	HVDB status on VDD_HV_B domain in FPM Shows the status of the high-voltage detect, HVDB, on the VDD_HV_B power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on VDD_HV_B is below high-voltage detect threshold or LPM. 1b - Voltage on VDD_HV_B is above high-voltage detect threshold and FPM.
8 HVDAS	HVDA status on VDD_HV_A domain in FPM Shows the status of the high-voltage detect HVDA on the VDD_HV_A power domain. The feature is only available in FPM and disabled in LPM. 0b - Voltage on VDD_HV_A is below high-voltage detect threshold or LPM. 1b - Voltage on VDD_HV_A is above high-voltage detect threshold and FPM.
7 —	Reserved
6 HVD15F	HVD15 flag on V15 domain in FPM PMC writes 1 to this field when the HVD15S status field changes. To clear HVD15F, write 1 to it. If enabled, HVD15F causes an interrupt request. 0b - HVD15S has not changed. 1b - HVD15S has changed.
5 —	Reserved
4 LVD5AF	LVD5A flag on VDD_HV_A domain in FPM PMC writes 1 to this field when LVD5AS status field changes. To clear LVD5AF, write 1 to it. If enabled, LVD5AF causes an interrupt request. 0b - LVD5AS has not changed. 1b - LVD5AS has changed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 HVD11F	HVD11 flag on V11 domain in FPM PMC writes 1 to this field when the HVD11S status field changes. To clear HVD11F, write 1 to it. If enabled, HVD11F causes an interrupt request. 0b - HVD11S has not changed. 1b - HVD11S has changed.
2 HVD25F	HVD25 flag on V25 domain in FPM PMC writes 1 to the HVD25F field when HVD25S status field changes. To clear HVD25F, write 1 to it. If enabled, HVD25F causes an interrupt request. 0b - HVD25S has not changed. 1b - HVD25S has changed.
1 HVDBF	HVDB flag on VDD_HV_B domain in FPM PMC writes 1 to the HVDBF field when HVDBS status field changes. To clear HVDBF, write 1 to it. If enabled, HVDBF causes an interrupt request. 0b - HVDBS has not changed. 1b - HVDBS has changed.
0 HVDAF	HVDA flag on VDD_HV_A domain in FPM PMC writes 1 to the HVDAF field when HVDAS status field changes. To clear HVDAF, write 1 to it. If enabled, HVDAF causes an interrupt request. 0b - HVDAS has not changed. 1b - HVDAS has changed.

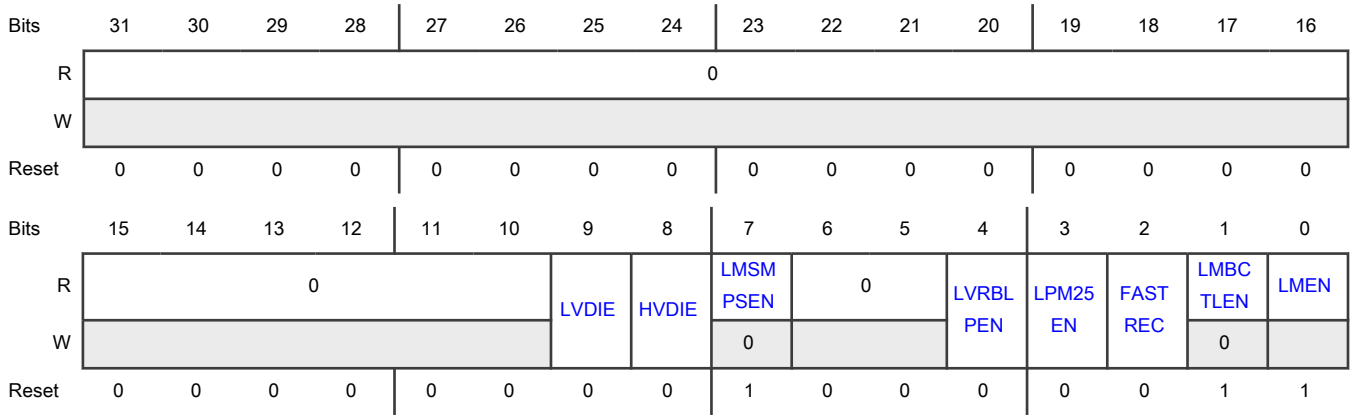
44.7.3 PMC Configuration Register (CONFIG)

Offset

Register	Offset
CONFIG	4h

Function
This register configures the various PMC options.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 LVDIE	Low voltage detect interrupt enable Enables hardware interrupt requests if LVD5AF is set. LVD interrupt must be disabled before going into LPM. 0b - LVD hardware interrupt is disabled (use polling). 1b - Request an LVD hardware interrupt when LVD5AF=1.
8 HVDIE	High voltage detect interrupt enable Enables hardware interrupt requests if any of the following flags is set: HVDAF, HVDBF, HVD25F, HVD11F. 0b - HVD hardware interrupt is disabled (use polling). 1b - Request an HVD hardware interrupt when HVDAF=1, HVDBF=1, HVD25F=1, or HVD11F=1.
7 LMSMPSEN	V15 Switched-mode power supply enable bit Enables the SMPS regulator (Switched-mode power supply), which regulates from VDD_DCDC down to 1.5V on V15 pin to supply the Last Mile regulator. As LMSMPSEN=1 after startup or reset, in case SMPS is not used, software must write LMBSMPSEN=0 after each reset to turn the feature off. Once LMSMPSEN=0 it can no longer be written 1 until next reset. 0b - Switched-mode power supply (SMPS) for V15 disabled 1b - Switched-mode power supply (SMPS) for V15 enabled
6-5 —	Reserved
4 LVRBLPEN	LVRBLP enable bit during LPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Controls whether the low-voltage reset detection (LVRBLP) on the VDD_HV_B power domain is active or inactive in LPM 0b - Low-voltage reset detection is disabled in LPM. 1b - Low-voltage reset detection is enabled in LPM.
3 LPM25EN	V25 domain enable bit during LPM Enables a low power V25 regulator and the low-voltage reset detection (LVR25LP) in LPM. In FPM this low power regulator is always off. 0b - V25 regulator and LVR25LP are disabled in LPM. 1b - V25 regulator and LVR25LP are enabled in LPM.
2 FASTREC	Fast recovery from LPM enable bit Controls the recovery time from LPM to FPM. This causes a higher current demand on V15, and this translates to a higher current demand on the primary side of the V15 supply. 0b - Normal recovery time from LPM 1b - Fast recovery time from LPM
1 LMBCTLEN	V15 external BJT enable bit This field must be set to 1 if external BJT between VDD_HV_A and V15 is used on the PCB. The base of this BJT must be connected to the VRC_CTRL pin and is controlled by the PMC to regulate a voltage of 1.5V on V15 pin to supply the Last Mile Regulator. As LMBCTLEN=1 after startup or reset, in case BJT is not used, software must write LMBCTLEN=0 after each reset to turn the feature off. Once LMBCTLEN=0 it can no longer be written 1 until next reset. 0b - External BCTL regulator for V15 disabled 1b - External BCTL regulator for V15 enabled
0 LMEN	Last Mile regulator enable bit Enables the Last Mile regulator, which regulates an external 1.5V voltage on V15 down to the core and logic supply (V11 power domain), which is typically 1.1V. As the Last Mile regulator is always enabled on this device, LMEN bit is read-only and always reads 1.

44.7.4 SMPS Configuration Register (SMPSCONFIG)

Offset

Register	Offset
SMPSCONFIG	8h

Function

This register configures the various options of the Switched-mode power supply (SMPS) generating the V15 (1.5V input supply to the last mile regulator).

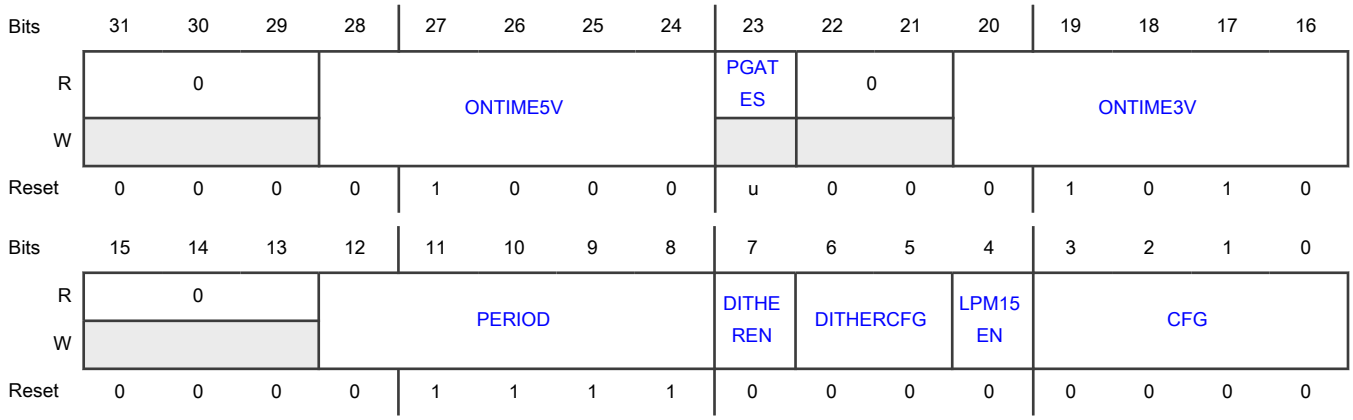
Table 254. SMPS configurations for driving PMOS_CTRL pin

CFG[3:0] bits	PMOS_CTRL Frequency	PMOS_CTRL Duty cycle 3V	PMOS_CTRL Duty cycle 5V
0000	470 kHz	58.8%	47.1%
0001	470 kHz	64.7%	52.9%
0010	470 kHz	52.9%	41.2%
0011	533 kHz	60%	46.7%
0100	533 kHz	66.7%	53.3%
0101	533 kHz	53.3%	40%
0110	421 kHz	57.9%	47.4%
0111	421 kHz	63.2%	52.6%
1000	421 kHz	52.6%	42.1%
1001 to 1110	Reserved	Reserved	Reserved
1111	8 MHz / (PERIOD[4:0]+1)	ONTIME3V[4:0] / (PERIOD[4:0]+1)	ONTIME5V[4:0] / (PERIOD[4:0]+1)

Table 255. 8 MHz IRC Dither configurations

DITHERCFG[1:0] bits	Dither Amplitude	Dither Frequency
00	+/- 0.4 MHz	400 kHz
01	+/- 0.6 MHz	286 kHz
10	+/- 0.8 MHz	222 kHz
11	+/- 1 MHz	182 kHz

Diagram



Fields

Field	Function
31-29	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
28-24 ONTIME5V	SMPS Duty cycle for 5V range These bits determine the duty cycle of the output signal at PMOS_CTRL pin. This duty cycle is applied while VDD_DCDC is greater or equal than 4V. It calculates as follows: Duty_pmos_ctrl = ONTIME3V[4:0] / (PERIOD[4:0] + 1)
23 PGATES	PMOS_CTRL Status Bit This read-only bit reflects the status of the PMOS_CTRL pin. 0b - PMOS_CTRL pin driven to VSS_DCDC (which is connect to GND) 1b - PMOS_CTRL pin driven to VDD_DCDC voltage
22-21 —	Reserved
20-16 ONTIME3V	SMPS Duty cycle for 3V range These bits determine the duty cycle of the output signal at PMOS_CTRL pin. This duty cycle is applied while VDD_DCDC is smaller than 4V. It calculates as follows: Duty_pmos_ctrl = ONTIME3V[4:0] / (PERIOD[4:0] + 1)
15-13 —	Reserved
12-8 PERIOD	SMPS Period These bits determine the frequency of the output signal at PMOS_CTRL pin. The frequency calculates as follows: Freq_pmos_ctrl = 8 MHz / (PERIOD[4:0] + 1)
7 DITHEREN	IRC Dither Enable This bit enables dithering of the 8MHz IRC. The amplitude and frequency of the dithering is determined by the DITHERCFG[1:0] bits. 0b - 8MHz IRC dithering disabled 1b - 8MHz IRC dithering enabled
6-5 DITHERCFG	IRC Dither Configuration Selects the IRC dithering amplitude and frequency. This feature spreads the frequency spectrum of driving the PMOS_CTRL pin to reduce radiated emission. To change the value: 1. Write 0 to DITHEREN. 2. Write the dither configuration (DITHERCFG[1:0]).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	3. Write 1 to DITHEREN. See Table 255 for configuration options.
4 LPM15EN	V15 domain enable bit during LPM Enables the V15 in LPM. This is useful for fast recovery to FPM when using the SMPS mode to generate the V15. This feature is only active in LPM, in FPM it is turned off. For this purpose there is a small LDO inside the PMC that regulates the V15 to target value during LPM. **NOTE** LPM15EN bit is only allowed to use, when using the SMPS to generate the V15. For other options to generate the V15 it is forbidden and software should always write 0 to LPM15EN. 0b - V15 not kept on target in LPM 1b - V15 kept on target in LPM
3-0 CFG	SMPS configuration select These bits select a configuration for frequency and duty cycle (ontime) of the Switched-mode power supply driving via PMOS_CTRL the external power FET according to Table 254. **NOTE** As seen in the table CFG[3:0] = 1111 allows for free customization of the PERIOD[4:0], ONTIME5V[4:0] and ONTIME3V[3:0] bits. If choosing this option consider carefully the value of these bits. To ensure the proper function of the SMPS, and to keep the EMI in check, the switching frequency and duty cycle must be programmed within a reasonable range.

44.7.5 Version ID register (VERID)

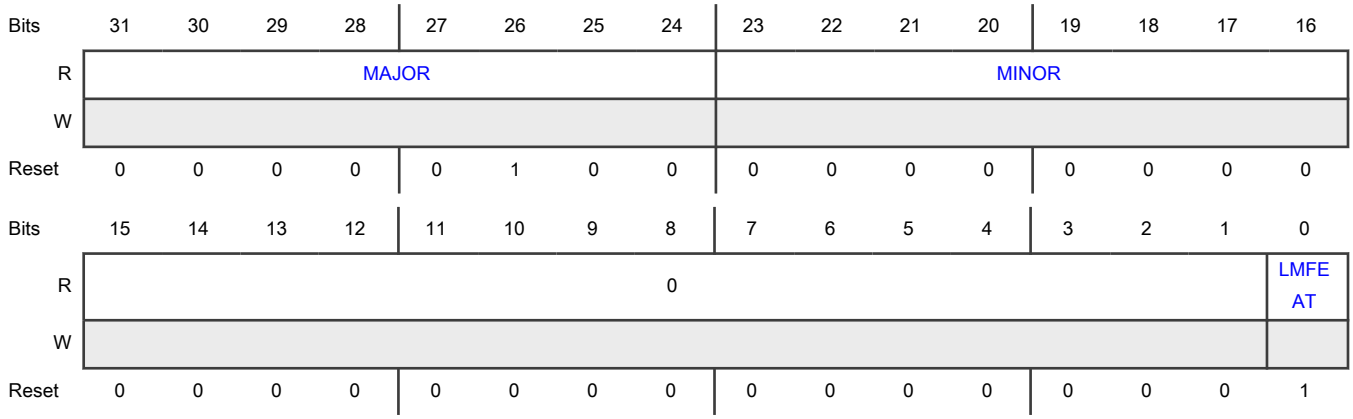
Offset

Register	Offset
VERID	Ch

Function

This register returns the major and minor version numbers of hardware implementation.

Diagram



Fields

Field	Function
31-24 MAJOR	Major version number Returns the version number for the specification
23-16 MINOR	Minor version number Returns the version number for the hardware implementation
15-1 —	Reserved
0 LMFEAT	Last Mile Regulator Feature This read-only field shows if the Last Mile regulator feature is available. 0b - No Last Mile regulator 1b - Last Mile regulator (1.5V to 1.1V) is available

44.8 Glossary

FPM	Full Performance mode
HVD	High voltage detect
IRC	Internal RC oscillator
LM	Last mile regulator
LPM	Low Performance mode
LVD	Low voltage detect
LVR	Low voltage reset
NVM	Nonvolatile memory
POR	Power on reset
XOSC	External crystal oscillator

SMPS	Switched-mode power supply

Chapter 45
Power Management Controller (PMC for S32K388 and S32K389)

45.1 Introduction

PMC is the power management controller for the S32K3 family of microcontrollers. It provides multiple power options to allow you to optimize power consumption for the level of functionality needed. It includes internal voltage regulators, POR, and the integrated low/high voltage detector system with reset (brown-out) capability. The voltage regulator requires a 3.3 V or 5 V input to generate all the required secondary supplies.

45.2 Features

- Combination of internal and external voltage regulator options, offering Run and Standby modes
- Active POR providing brown-out detect
- LVR for all system-relevant power domains
- LVD and HVD as indication for software
- Two bandgaps to enable independent supply generation and monitoring
- Two independent LVR monitors for each safety-relevant power supply domain

45.3 Modes of operation

PMC provides two basic modes of operation for voltage regulators and monitors:

- FPM, which is used on chip-level in Run modes (for high-current consumption)
- LPM, which is used on chip-level for Standby modes (for low-current consumption)

45.4 Block diagram

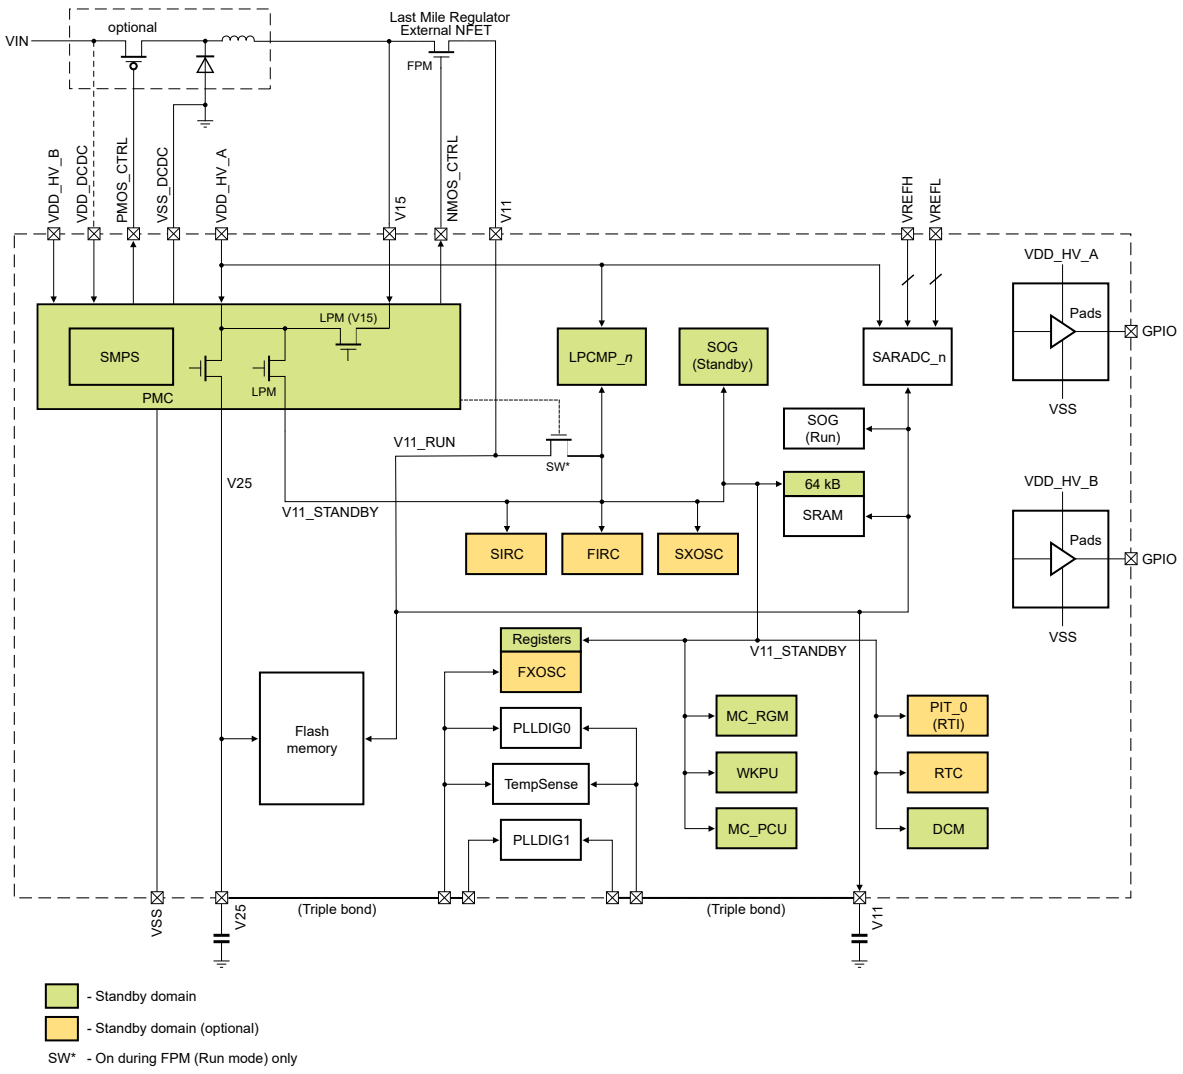


Figure 187. PMC block diagram

45.5 Signals

Table 256. Signal description

Signal	I/O	Description
VDD_HV_A	Supply input	VDD_HV_A is the primary high-voltage supply input to PMC. It is used for the PMC internal precision references. After the VDD_HV_A domain is powered up, you must keep it powered at all times of operation (FPM and LPM).
VDD_HV_B	Supply input	VDD_HV_B is the secondary high-voltage supply input that PMC supervises. After the VDD_HV_B domain is powered up, you must keep it powered at all times of operation (FPM and LPM).

Table continues on the next page...

Table 256. Signal description (continued)

Signal	I/O	Description
V25	Supply output	A fully integrated low-dropout linear voltage regulator drives this V25 power supply domain. It supplies the flash memory and (via a double bond) the clock modules.
V15	Supply input	The V15 supply is generated by the SMPS or by an external source (see Figure 187). PMC uses this pin to measure the voltage level on V15. Optionally, for SMPS, a PMC internal trickle LDO can sustain the V15 supply in LPM.
NMOS_CTRL	Output	NMOS_CTRL connects to the gate of an external NFET, which is used to regulate V15 down to V11 (core voltage). For the 1.1 V core regulator, an external NFET with low-threshold voltage (v_{th} smaller than 1.0 V) is needed, for example, Vishay SQ2310ES. Additionally 1 nF at the gate is required for stability reasons.
V11	Supply input	V11 is the core and logic supply. It is driven by the external NFET which is controlled by a linear regulator inside PMC.
VSS	Ground	VSS must be grounded. All VSS pins need to be externally connected to the same ground node.
VDD_DCDC	Supply input	VDD_DCDC is the power supply domain for the SMPS gate driver. It must be shorted with the source voltage of the external power FET. An off-chip decoupling capacitor between VDD_DCDC and ground is required. See Datasheet for the recommended value. **NOTE** If SMPS (DCDC) mode is used and the PMC is in low power mode, it must be ensured that SMPS supply input VDD_DCDC is fully operational and loadable before wake-up from low power mode. Otherwise a low voltage reset might occur on wake-up.
VSS_DCDC	Ground	VSS_DCDC is the power ground for the SMPS gate driver. It must be shorted with the main ground node and the ground node of the external Schottky diode.
PMOS_CTRL	Output	PMOS_CTRL is the gate driver output for the external power FET for the SMPS regulator.

45.6 Functional description

45.6.1 Reset

The POR and all LVRs are combined into one single MCU POR.

After an MCU POR event, you can determine which power domain caused the event by reading LVSC[PORF] and the relevant LVR*x* field (for example, LVSC[LVR11LPF]).

After an initial power ramp-up of the MCU, PMC writes 1 to LVSC[PORF] and all LVSC[LVR*x*] fields. The Go/Nogo fields have an arbitrary value.

NOTE

After an initial power ramp-up, you must write FFFFFFFFh to LVSC to clear all flags.

Because the flags are sticky bits, you must clear them before using them. Doing so makes it possible to track and debug the source of the problem by reading the Low Voltage Status and Control (LVSC) fields, if there is an unexpected MCU POR.

45.6.2 Interrupts

PMC includes two interrupt sources:

- HVD: Combines all HVD monitors into a single interrupt source. Enable this interrupt with CONFIG[HVDIE].
- LVD: uses the LVD5A as interrupt source. Enable this interrupt with CONFIG[LVDIE].

See PMC Configuration (CONFIG) and Low Voltage Status and Control (LVSC) for details.

45.7 PMC register descriptions

45.7.1 PMC memory map

This section includes the PMC module memory map and detailed descriptions for all the registers. Registers marked "Reserved" should not be modified from their reset value by a write access.

PMC base address: 402E_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Low Voltage Status and Control (LVSC)	32	RW	See section
4h	PMC Configuration (CONFIG)	32	RW	0000_0081h
8h	SMPS Configuration (SMPSCONFIG)	32	RW	See section
Ch	Version ID (VERID)	32	R	0600_0001h

45.7.2 Low Voltage Status and Control (LVSC)

Offset

Register	Offset
LVSC	0h

Function

Contains status and control fields that support the low-voltage reset and LVD or HVD function. When the PMC is in LPM, the LVD or HVD systems are disabled.

For flags that are not affected by reset (POR flag, all LVR flags, all GNG flags), if a reset occurs at the same time as an attempt to clear the flags (by writing 1), the flag value is not defined appropriately. In this case, you need to clear the flag again after exit from reset.

For the GNG flags, if a GNG event occurs at the same time as the GNG flag is read, the flag value might not be defined appropriately. In this case, you need to read the flag twice and consider the value only if it both read values match.

14 HVD15S	HVD15 Status On V15 Domain In FPM Shows the status of the high-voltage detect, HVD15, on the V15 power domain. This feature is available only in FPM and is disabled in LPM. 0b - Below threshold or LPM 1b - Above threshold and FPM
13 —	Reserved
12 LVD5AS	LVD5A Status On VDD_HV_A Domain In FPM Shows the status of the 5 V LVD, LVD5A, on the VDD_HV_A power domain. This monitor indicates if the voltage is below a certain threshold, which is set slightly below 4.5 V (see the data sheet for the exact value). This feature is available only in FPM and is disabled in LPM. After a reset or wake-up from LPM, you must clear the LVD5AF flag and check the status field LVD5AS to determine the voltage level on the VDD_HV_A supply. 0b - Above threshold 1b - Below threshold

Field	Function
11 HVD11S	HVD11 Status On V11 Domain In FPM Shows the status of HVD11 on the V11 power domain. This feature is available only in FPM and is disabled in LPM. 0b - Below threshold or LPM 1b - Above threshold and FPM
10 HVD25S	HVD25 Status On V25 Domain In FPM Shows the status of the high-voltage detect, HVD25, on the V25 power domain. This feature is available only in FPM and is disabled in LPM. 0b - Below threshold or LPM 1b - Above threshold and FPM
9 HVDBS	HVDB Status On VDD_HV_B Domain In FPM Shows the status of the high-voltage detect, HVDB, on the VDD_HV_B power domain. This feature is available only in FPM and is disabled in LPM. 0b - Below threshold or LPM 1b - Above threshold and FPM
8 HVDAS	HVDA Status On VDD_HV_A Domain In FPM Shows the status of the high-voltage detect HVDA on the VDD_HV_A power domain. This feature is available only in FPM and is disabled in LPM. 0b - Below threshold or LPM 1b - Above threshold and FPM
7 —	Reserved
6 HVD15F	HVD15 Flag On V15 Domain In FPM PMC writes 1 to this field when the HVD15S status field changes. To clear HVD15F, write 1 to it. If enabled, HVD15F causes an interrupt request. 0b - Not changed 1b - Changed
5 —	Reserved
4 LVD5AF	LVD5A Flag On VDD_HV_A Domain In FPM PMC writes 1 to this field when the LVD5AS status field changes. To clear LVD5AF, write 1 to it. If enabled, LVD5AF causes an interrupt request. 0b - Not changed

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Changed
3 HVD11F	HVD11 Flag On V11 Domain In FPM PMC writes 1 to this field when the HVD11S status field changes. To clear HVD11F, write 1 to it. If enabled, HVD11F causes an interrupt request. 0b - Not changed 1b - Changed
2 HVD25F	HVD25 Flag On V25 Domain In FPM PMC writes 1 to this field when the HVD25S status field changes. To clear HVD25F, write 1 to it. If enabled, HVD25F causes an interrupt request. 0b - Not changed 1b - Changed
1 HVDBF	HVDB Flag On VDD_HV_B Domain In FPM PMC writes 1 to this field when the HVDBS status field changes. To clear HVDBF, write 1 to it. If enabled, HVDBF causes an interrupt request. 0b - Not changed 1b - Changed
0 HVDAF	HVDA Flag On VDD_HV_A Domain In FPM PMC writes 1 to this field when the HVDAS status field changes. To clear HVDAF, write 1 to it. If enabled, HVDAF causes an interrupt request. 0b - Not changed 1b - Changed

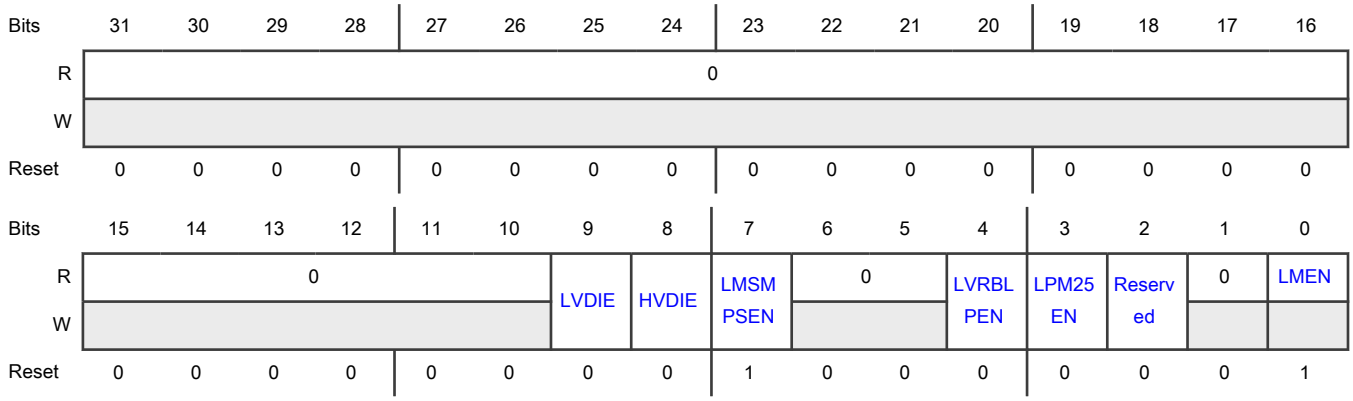
45.7.3 PMC Configuration (CONFIG)

Offset

Register	Offset
CONFIG	4h

Function
Configures the various PMC options.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 LVDIE	Low Voltage Detect Interrupt Enable Enables hardware interrupt requests if LVSC[LVD5AF] = 1. The LVD interrupt must be disabled before entering LPM. If enabled, there is a request for an LVD hardware interrupt. If disabled, LVD hardware interrupt is disabled (use polling). 0b - Disables 1b - Enables
8 HVDIE	HVD Interrupt Enable Enables hardware interrupt requests if any of the following fields = 1: • LVSC[HVDAF] • LVSC[HVDBF] • LVSC[HVD25F] • LVSC[HVD11F] 0b - Disables 1b - Enables
7 LMSMPSEN	V15 Switched-Mode Power Supply Enable Enables the SMPS regulator (switched-mode power supply), which regulates from VDD_DCDC down to 1.5 V on the V15 pin to supply the last mile regulator. Because LMSMPSEN = 1 after startup or reset, if SMPS is not used, you must write 0 to LMBSMPSEN after each reset to turn the feature off. When LMSMPSEN = 0, you can no longer write 1 to it until the next reset. 0b - Disables 1b - Enables
6-5	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
4 LVRBLPEN	LVRBLP Enable During LPM Enables low-voltage reset detection (LVRBLP) on the VDD_HV_B power domain in LPM. 0b - Disables 1b - Enables
3 LPM25EN	V25 Domain Enable During LPM Enables a low-power V25 regulator and the low-voltage reset detection (LVR25LP) in LPM. In FPM, this low-power regulator is always off. 0b - Disables 1b - Enables
2 —	Reserved
1 —	Reserved
0 LMEN	Last Mile Regulator Enable Enables the last mile regulator, which regulates an external 1.5 V voltage on V15 down to the core and logic supply (V11 power domain), which is typically 1.1 V. Because the last mile regulator is always enabled on this chip, LMEN always reads 1.

45.7.4 SMPS Configuration (SMPSCONFIG)

Offset

Register	Offset
SMPSCONFIG	8h

Function

Configures the various options of the switched-mode power supply (SMPS) generating V15 (1.5 V input supply to the last mile regulator).

Table 257. SMPS configurations for driving the PMOS_CTRL pin

Fields

Field	Function
31-29 —	Reserved
28-24	SMPS Duty Cycle For 5 V Range

Table continues on the next page...

Table continued from the previous page...

Field	Function
ONTIME5V	Determines the duty cycle of the output signal at the PMOS_CTRL pin. This duty cycle is applied when VDD_DCDC is greater than or equal to 4 V. The duty cycle is calculated as follows: Duty_pmos_ctrl = ONTIME3V[4:0] ÷ (PERIOD[4:0] + 1)
23 PGATES	PMOS_CTRL Status Reflects the status of the PMOS_CTRL pin. If = 0, note that VSS_DCDC is connected to GND. 0b - Driven to VSS_DCDC 1b - Driven to VDD_DCDC
22-21 —	Reserved
20-16 ONTIME3V	SMPS Duty Cycle For 3 V Range Determines the duty cycle of the output signal at the PMOS_CTRL pin. This duty cycle is applied when VDD_DCDC is smaller than 4 V. The duty cycle is calculated as follows: Duty_pmos_ctrl = ONTIME3V[4:0] ÷ (PERIOD[4:0] + 1)
15-13 —	Reserved
12-8 PERIOD	SMPS Period Determines the frequency of the output signal at the PMOS_CTRL pin. The frequency is calculated as follows: Freq_pmos_ctrl = 8 MHz ÷ (PERIOD[4:0] + 1)
7 DITHEREN	IRC Dither Enable Enables dithering of the 8 MHz IRC. The amplitude and frequency of the dithering is determined by the DITHERCFG[1:0] bits. 0b - Disables 1b - Enables
6-5 DITHERCFG	IRC Dither Configuration Selects the IRC dithering amplitude and frequency. This feature spreads the frequency spectrum of driving the PMOS_CTRL pin to reduce radiated emission. To change the value: 1. Write 0 to DITHEREN. 2. Write the dither configuration (DITHERCFG[1:0]). 3. Write 1 to DITHEREN. See Table 258 for configuration options.
4	V15 Domain Enable During LPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
LPM15EN	Enables V15 in LPM. This is useful for fast recovery to FPM when using the SMPS mode to generate V15. This feature is active only in LPM, and is turned off in FPM. For this purpose, there is a small LDO inside the PMC that regulates V15 to the target value during LPM. **NOTE** LPM15EN is only used if SMPS generates V15. All other options to generate V15 are forbidden, and in those cases you must always write 0 to LPM15EN. 0b - Not kept on target 1b - Kept on target
3-0 CFG	SMPS Configuration Select Selects a configuration for frequency and duty cycle (on-time) of the switched-mode power supply, which drives (via PMOS_CTRL) the external power FET, according to Table 257. **NOTE** As seen in the table, CFG[3:0] = 1111 allows for free customization of PERIOD[4:0], ONTIME5V[4:0], and ONTIME3V[3:0]. If you choose this option, you must carefully consider the value of these bits. To ensure proper functioning of SMPS, and to keep EMI in check, you must program the switching frequency and duty cycle within a reasonable range.

45.7.5 Version ID (VERID)

Offset

Register	Offset
VERID	Ch

Function

Returns the major and minor version numbers of hardware implementation.

Field	Function
31-24 MAJOR	Major Version Number Returns the version number for the specification. K344 = 2, K31x = 3, K358 = 4, K396 = 5, K388 = 6
23-16 MINOR	Minor Version Number Returns the version number for the hardware implementation.
15-1 —	Reserved
0 LMFEAT	Last Mile Regulator Feature Indicates whether the last mile regulator feature (1.5 V to 1.1 V) is available. 0b - Not available 1b - Available

45.8 Glossary

FPM	Full Performance mode
HVD	High voltage detector
IRC	Internal RC oscillator
LM	Last mile regulator
LPM	Low Performance mode
LVD	Low voltage detector
LVR	Low voltage reset
NVM	Nonvolatile memory
POR	Power on reset
XOSC	External crystal oscillator
SMPS	Switched-mode power supply

Chapter 46
Mode Entry Module (MC_ME)

46.1 Chip-specific MC_ME information

46.1.1 MC_ME modes

This chip implements these modes:

- Reset
- Run
- Standby

The chip always enters Run mode after exiting Reset mode wherein you can configure the chip to perform its computational and communication functions. In Run mode:

- The chip remains fully powered. The boot core is the only core enabled on Run entry.
- You can enable and disable application cores and peripherals as needed, based on functional and power requirements.
- You can configure the pins and self-test as needed. See "Self-Test programming sequence" section in the STCU2 chapter for the self-test programming sequence to be followed before initiating self-test, in which:
  - Pins are safe-stated.
  - No computational or communication activities are possible.
- The chip automatically enters Reset mode after self-test (BIST) is complete.

46.1.2 Core operation modes

The Cortex-M7 cores in the chip support these two modes of operation:

- Decoupled/independent operation
- Coupled/lockstep operation

The device configuration clients (utest_misc DCF client) control these modes of operation. See the DCF clients file attached to this document for details.

46.1.3 MC_ME partition mapping of cores and peripherals

MC_ME provides registers and interface signals to support multiple partitions. These MC_ME partitions are different from the chip's LBIST partitions described in the "Safety Overview" chapter. This chip has three MC_ME partitions:

- Partition 0: Contains application cores and the on/off-platform slots on AIPS_0 bridge
- Partition 1: Contains the on/off-platform slots on AIPS_1 bridge
- Partition 2: Contains the on/off-platform slots on AIPS_2 bridge

Table 259 and Table 260 specify the core and peripheral mapping on MC_ME partitions and their associated clock gating possibilities.

MC_ME also provides provisions to control the booting address for application cores, which can be configured to start from a nondefault address location by appropriately configuring PRTN*x*_CORE*n*_ADDR[ADDR].

46.1.4 Core clock gating

MC_ME has individual core-clock enable fields that gate the application core clocks, which can also be clock gated by executing Waiting for Interrupt (WFI).

You can enable the application cores by configuring the respective CCE fields. See Application core initialization process and Application core shutdown process for proper initialization and shutdown of application cores. There is no clock control for the HSE_B core. It needs to be only put into WFI if required to be shutdown (for example, in Standby mode).

Table 259. MC_ME partition core mapping

Core	MC_ME partition	MC_ME clock enable register field
Cortex-M7_0	0	MC_ME.PRTN0_CORE0_PCONF[CCE]
Cortex-M7_1 [1]	0	MC_ME.PRTN0_CORE1_PCONF[CCE]
Cortex-M7_2 [1], [2]	0	MC_ME.PRTN0_CORE4_PCONF[CCE]
Cortex-M7_3 [1], [3]	0	MC_ME.PRTN0_CORE3_PCONF[CCE]

1. Not present on S32K312 and S32K311
2. Only present on S32K388, S32K389, S32K358, S32K348, S32K338, and S32K328
3. Only present on S32K388 and S32K389

46.1.5 Peripheral clock gating

See Peripheral initialization process and Peripheral shutdown process for proper initialization and shutdown of peripherals. See Table 260 for peripheral clock gating possibilities. This table details clock gating possibilities of all chips. For applicable modules/module instances see corresponding chip-specific section of the module. "MC_ME memory map" section the details clock gating possibilities of S32K388/S32K389 chip.

The application core can program the reserved configurations.

NOTE

Before accessing the registers of a peripheral to start using it, its clock must be turned on, otherwise, a Hard-Fault event will occur.

1. Applicable for S32K388 and S32K389 only.
2. Applicable for S32K328, S32K338, S32K348, S32K358, S32K388, and S43K389 only.
3. Applicable for S32K389 only.
4. Applicable for S32K314, S32K324, S32K344, S32K328,S32K338, S32K348, S32K358, S32K388, and S32K389 only.
5. Applicable for S32K322, S32K324, S32K328, S32K338, S32K358, S32K388, and S32K389 only.
6. Reserved for S32K310, S32K311, and S32K312.
7. Applicable for S32K310, S32K311, S32K312, S32K322, S32K341, S32K342, S32K314, S32K324, and S32K344

Table 261. PRTN1_COFB0_CLKEN[REQ22]

Bit filed	Description
REQ22	Clock enable This bit provides the clock enable control for block 22 in partition 1. 0b - Clock is turned off. 1b - Clock is turned on.

8. Reserved for S32K310 and S32K311.
9. Applicable for S32K328, S32K338, S32K348, S32K358, S32K388, and S32K389 only.
10. Applicable for S32K338, S32K388 and S32K389 only.
11. Reserved for S32K310, S32K311, S32K322, S32K341, and S32K342.
12. Applicable for S32K310, S32K311, and S32K312 only.
13. All the corresponding MC_ME slots must be configured to access the peripheral. For example, PRTN1_COFB3_CLKEN[REQ112], PRTN1_COFB3_CLKEN[REQ113], PRTN1_COFB3_CLKEN[REQ114], and PRTN1_COFB3_CLKEN[REQ115] must be configured to access AES Accelerator.
14. Applicable for S32K322, S32K341, S32K342, S32K314, S32K324, S32K344, S32K388, and S32K389
15. Applicable for S32K322, S32K324, S32K328, S32K338, S32K358, S32K388, and S32K389 only.
16. Applicable for S32K338, S32K388, and S32K389 only.
17. Applicable for S32K322, S32K341, S32K342, S32K314, S32K324, and S32K344 only.

Table 262. PRTN2_COFB1_CLKEN[REQ32]

Bit filed	Description
REQ32	Clock enable This bit provides the clock enable control for block 32 in partition 2. 0b - Clock is turned off. 1b - Clock is turned on.

18. Applicable for S32K328, S32K338, S32K348, and S32K358 only.

Table 263. PRTN2_COFB1_CLKEN[REQ57]

Bit filed	Description
REQ57	Clock enable This bit provides the clock enable control for block 57 in partition 2. 0b - Clock is turned off. 1b - Clock is turned on.

46.1.6 Application core initialization process

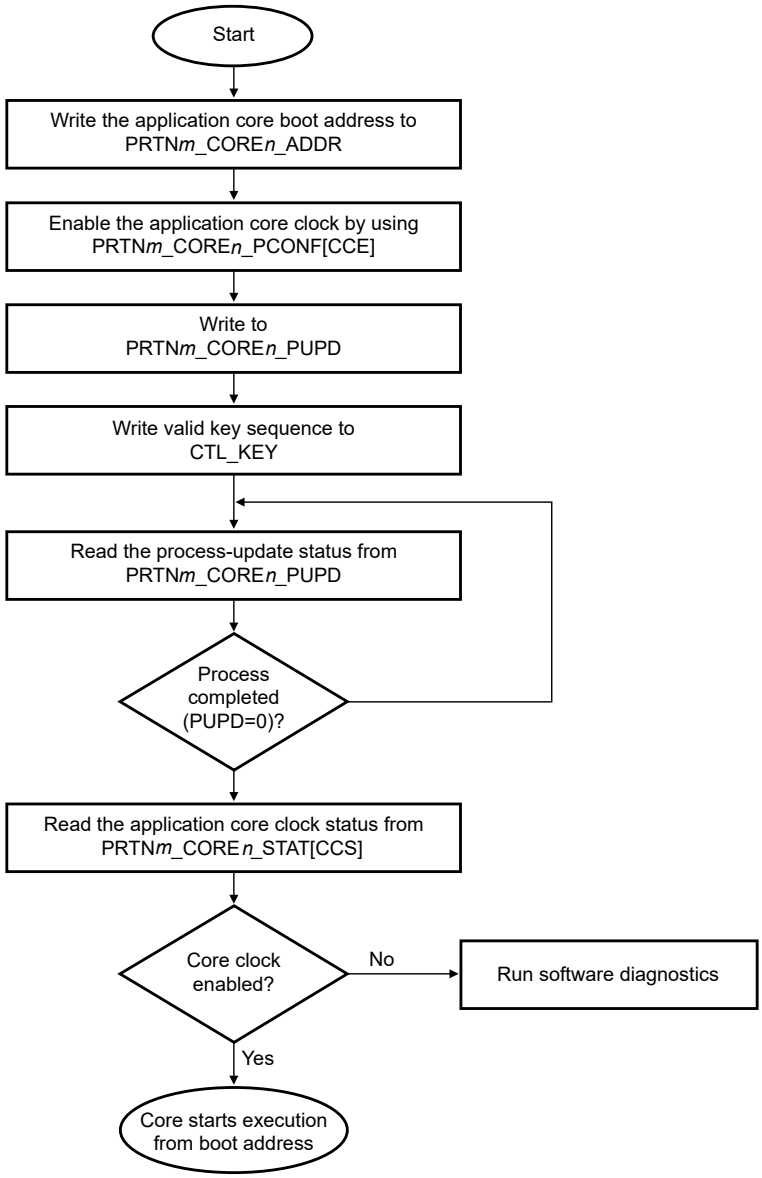

Figure 188. Application core initialization process

46.1.7 Application core shutdown process

If a debugger is attached to the chip and application debug is enabled, the application core continues running if you write 0 to MDM_AP.MDMAPCT[CM7_*n*_CORE_ACCESS].

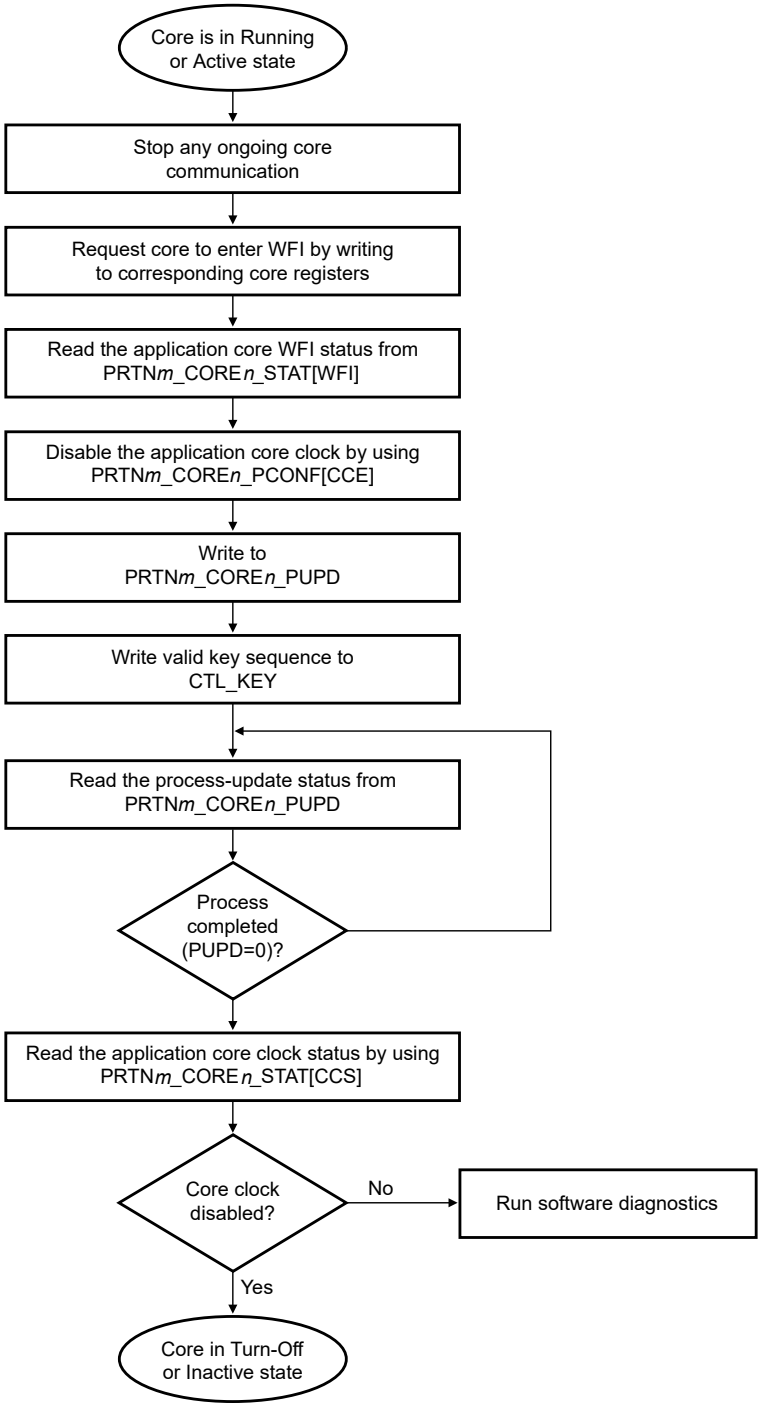

Figure 189. Application core shutdown process

46.1.8 Peripheral initialization process

You cannot control all the peripherals. For example, you cannot turn on and turn off the peripherals required for chip functionality across reset or power-up. They always remain on.

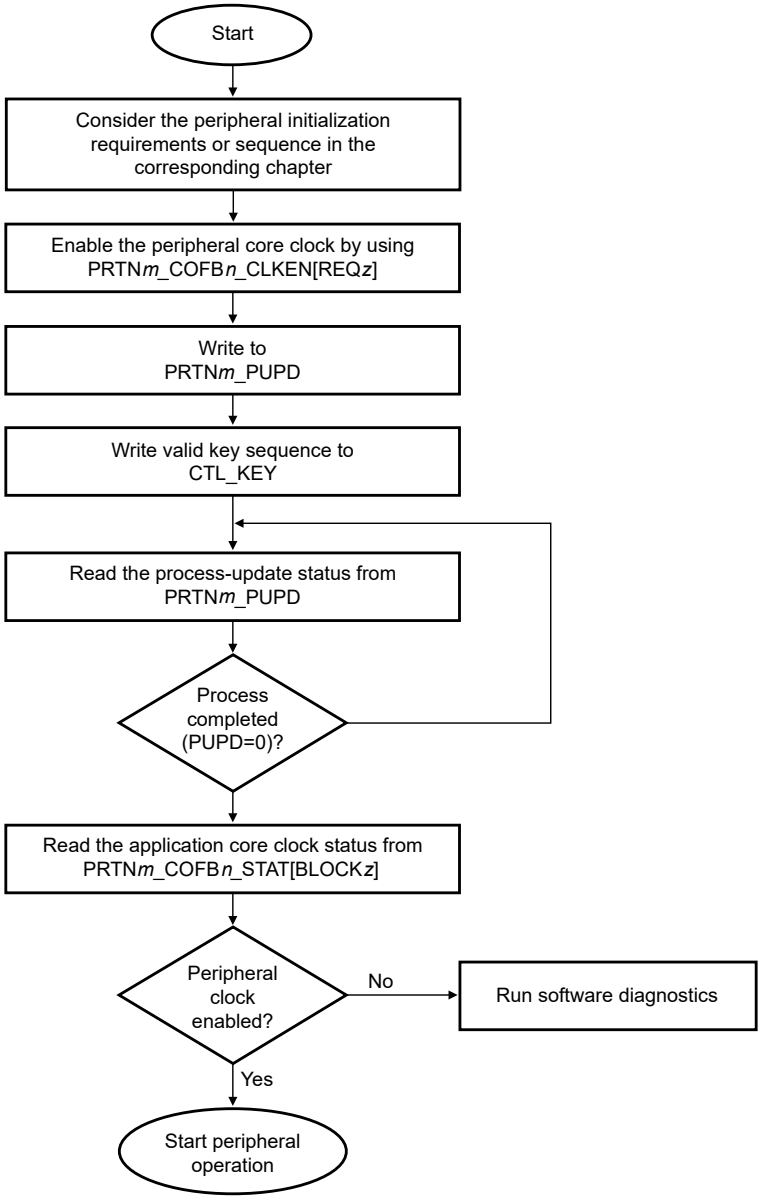

Figure 190. Peripheral initialization process

46.1.9 Peripheral shutdown process

You cannot control all the peripherals. For example, you cannot turn on and turn off the peripherals required for chip functionality across reset or power-up. They always remain on.

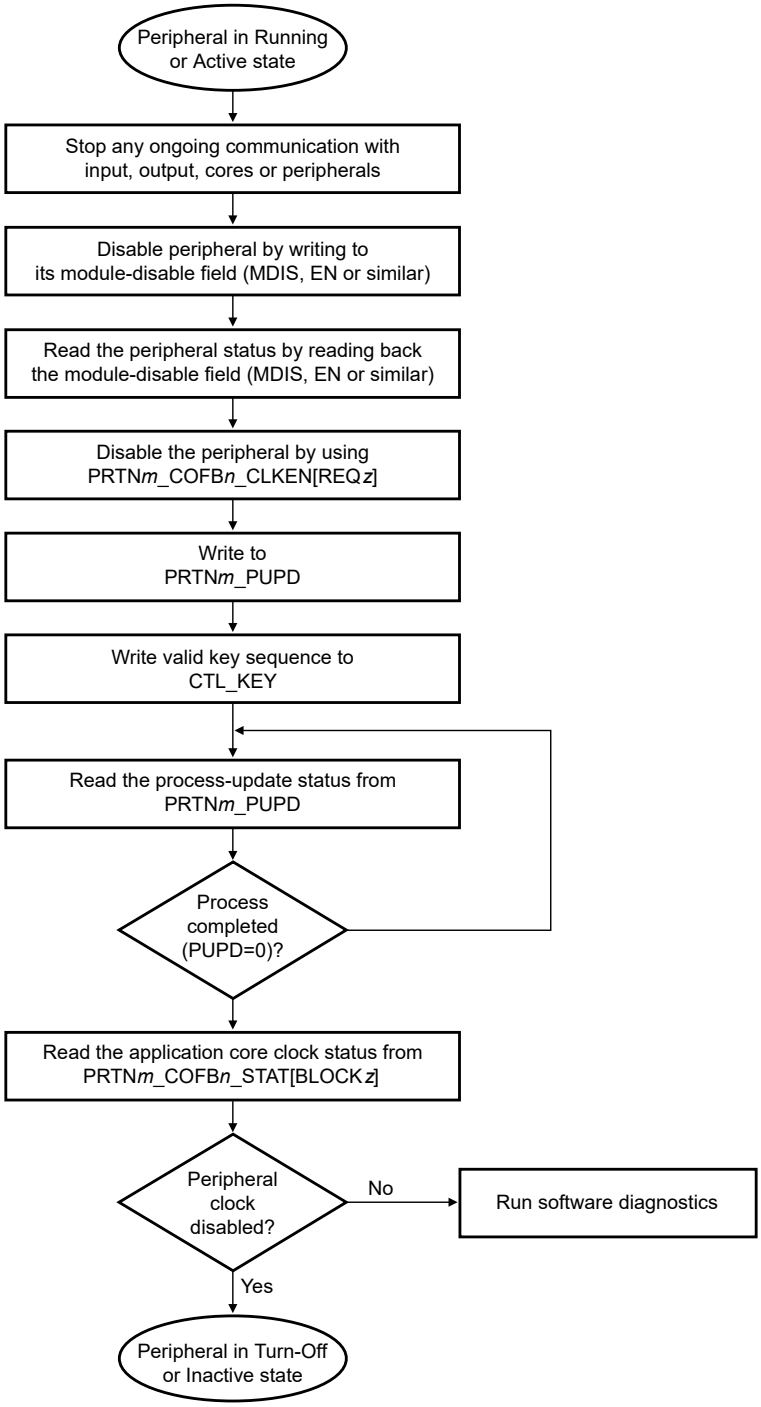

Figure 191. Peripheral shutdown process

46.2 Introduction

The MC_ME module generates control signals for a set of modules of the SoC. The set of signals are defined in corresponding 'Partition Configuration Registers'. It also implements a software-based mechanism for initiating a functional and destructive reset sequence and standby entry handshake with power management of SoC. See Figure 192 for the MC_ME block diagram.

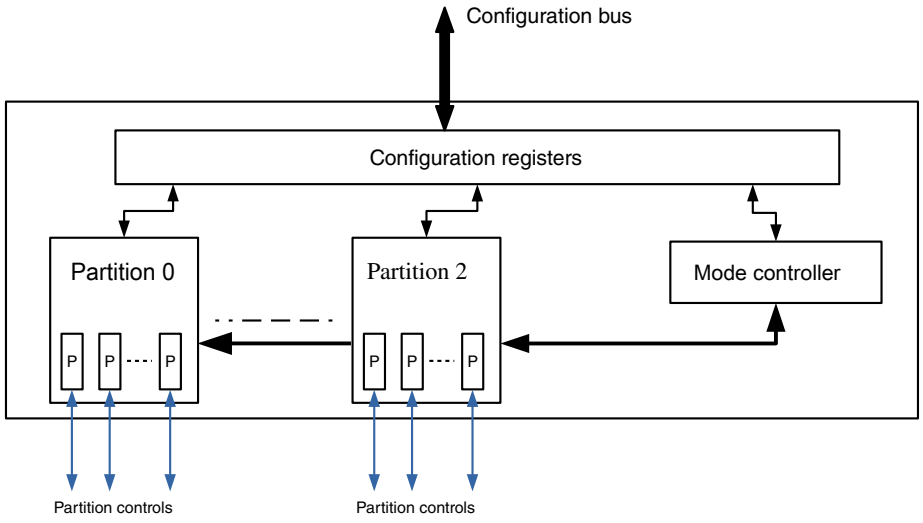

Figure 192. MC_ME block diagram

46.3 Features

MC_ME includes the following features:

- 3 logic partitions implementation and their controls
- Core clock controls
- Partition clock control
- Control mechanism for initiating a destructive or functional reset sequence to MC_RGM
- Control mechanism for initiating standby mode entry for SoC

The logic partition inside MC_ME refers to a certain group of on-chip resources (or IP blocks) that are clubbed together to represent a single 'Partition' inside MC_ME. The MC_ME partition can be the same or different than an LBIST partition. Each of the MC_ME partitions implements a certain number of hardware processes. These hardware processes provide a mechanism to regulate various control signals provided to or received from the IP blocks. The corresponding status signals can also be monitored from MC_ME register(s). Each of the hardware processes is bound to finish in 512 cycles of the MC_ME register configuration clocks. Therefore, the hardware processes are non blocking in nature. Mismatch in the expected versus actual status of any hardware process is controlled by a pre-defined software.

46.4 Partition processes

Each of the processes inside the partition controls register space and corresponds to a control signal provided to that partition. A partition can include a core, or COFBs, or both. The MC_ME hardware processes provide control and status via signals provided to partitions. Each partition can be assigned a signal for control and a signal for status. Each of the control signals implements functionality for the partition. For example, clock gating and peripheral control.

The hardware process can be triggered and monitored using a set of three registers:

- Configuration register; for example, Partition n Process Configuration register
- Update register; for example, Partition n Process Update register
- Status register; for example, Partition n Status register

Similar registers exist for cores inside the partition.

The process setup and triggering procedure is shown in Figure 193. Each of the processes is independent of others and can be triggered or re-triggered in parallel or sequential to other processes. The triggering or re-triggering mechanism remains the same.

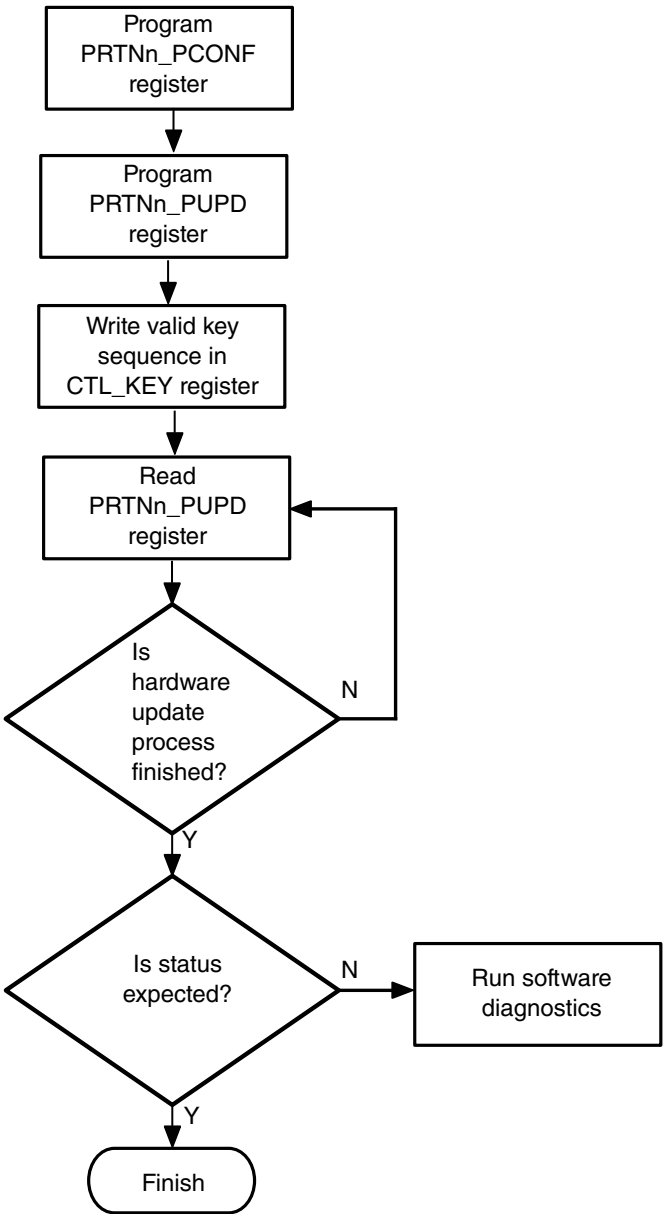

Figure 193. Partition process setup procedure

All the hardware processes are bound to finish in 512 cycles of the MC_ME configuration clock. If the actual and the expected status for a process does not match, then the diagnostics is left as a software responsibility. The software diagnostic can include further wait cycles for the status to match.

46.5 Mode transition

MC_ME implements a mode transition mechanism, whereby the mode of operation for SoC can be changed. Then module implements a mechanism that can lead to:

- Destructive reset
- Functional reset
- Standby mode entry

Destructive reset and functional reset requests from MC_ME are non-retractable transitions. After it is initiated, the other MC_ME functionality is rendered unusable and bus errors are provided for upcoming access to the MC_ME register until a reset sequence is executed by MC_RGM. Hence, it is vital that MC_RGM should never ignore or gate the reset requests from MC_ME.

For transition into the standby mode, the software should ensure that required IP blocks such as clock sources and I/O communication are in their respective inactive states before initiating a standby mode transition to MC_ME. After MC_ME initiates a power down sequence request, it cannot be retracted. The SoC enters a standby power down sequence and then reenter power-up sequence even for cases where the standby wakeup happens right at the time of initiating a power-down sequence request.

Steps for initiating the MC_ME mode transition:

1. Setup the MODE_CONF register with the corresponding target mode bit set to logic-1.
2. Perform the same update as done in the MODE_CONF register on the CONF_UPD register.
3. Write the valid control key (0x5AF0) on the CTL_KEY register.
4. Write the valid invert control key (0xA50F) on the CTL_KEY register.

Mode transition to MC_ME is initiated, after the sequence mentioned above is completed.

In step 1, if both FUNC_RST and DEST_RST in Mode Configuration Register (MODE_CONF) are 1:

- After step 4 is complete, MC_ME initiates a mode transition to a destructive (not functional) reset.
- After the chip exits reset, MC_RGM records that both MC_ME's destructive reset and MC_ME's functional reset were the reset source.

NOTE

Any hardware partition processes setup, along with mode transition, is executed in parallel to the mode transition of MC_ME.

46.6 Standby entry

MC_ME provides hardware processes that implement shutdown sequencing of on-chip resources, such as cores and COFBs. The standby entry sequencing can be achieved or implemented using these hardware processes. The order of the hardware process is determined by the software and MC_ME. It requires no restriction in sequencing of the operation. Following is an example sequence for initiating a power-down sequence for entering the standby mode for SoC. The standby entry sequence should include (but not limited to) the following steps:

1. Setting up wakeup lines
2. Shutting down cores and COFBs
3. Switching all MC_CGM muxes to FIRC with PCFS
4. Powering down all clock sources except FIRC
5. Setting up MC_ME using the main core and initiating a standby mode transition
6. Executing WFI instruction on the main core (per Arm specification)

46.6.1 Application core shutdown

This section describes a mechanism for shutting down an application core. The sequence proposed here is extendible with the housekeeping tasks required for other IPs. Each of the tasks mentioned in the following sequence, can be further integrated with an SoC-specific task.

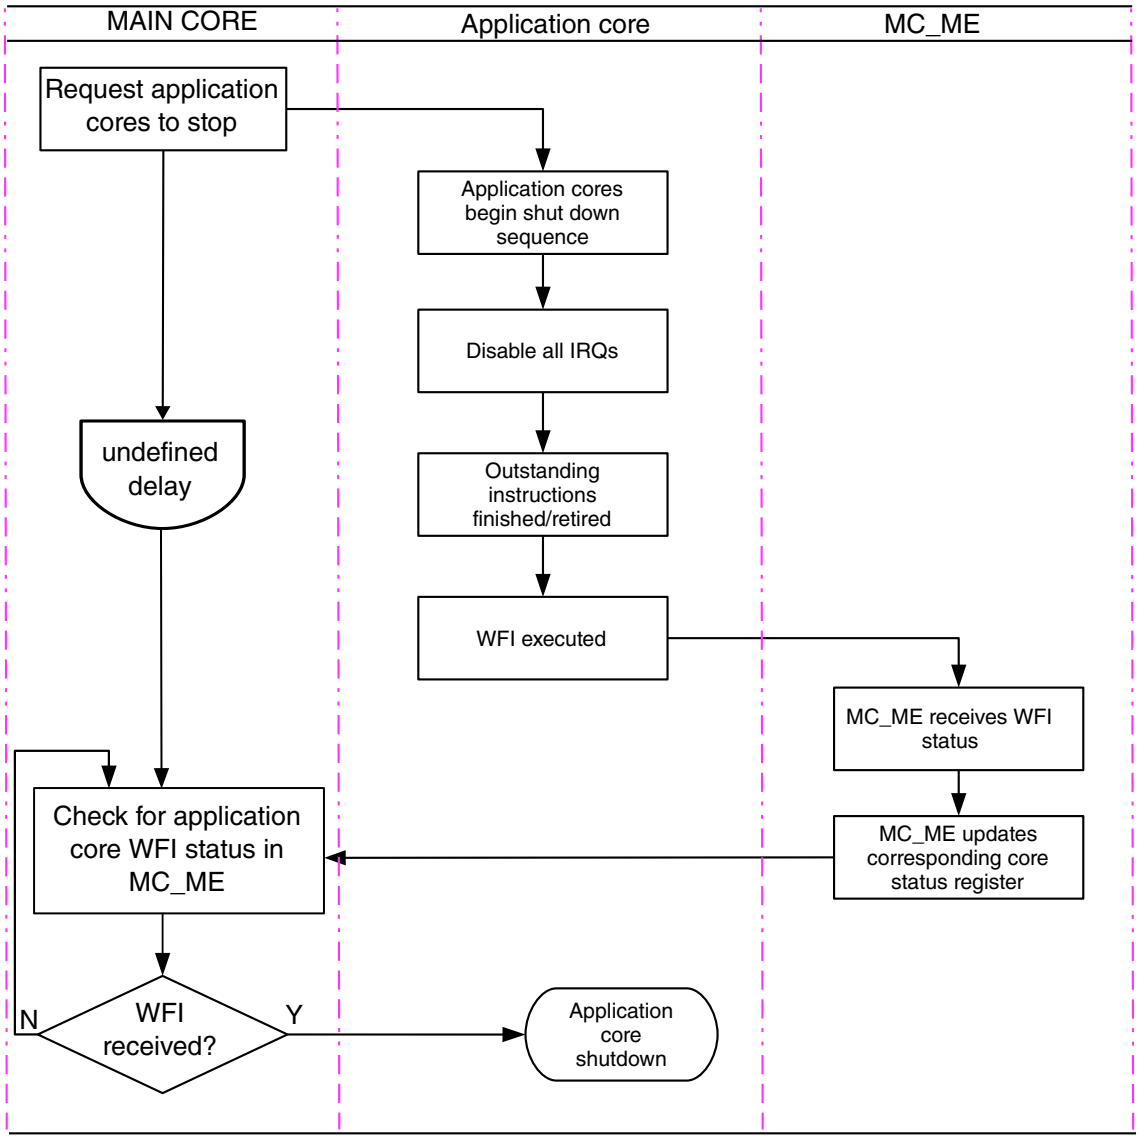

Figure 194. Application core shutdown

After the application core is shutdown, the main core can optionally decide to gate the respective core clock using the corresponding core clock hardware process.

46.6.2 Main core shutdown and standby entry

This section describes standby entry sequence along with the main core shutdown. This sequence should only be initiated after SoC is ready for entering standby and has completed all the housekeeping activities. It is necessary that the main core has completed all the operations pertaining to other (application cores) and is the last active core before initiating the standby entry sequence. See Figure 195.

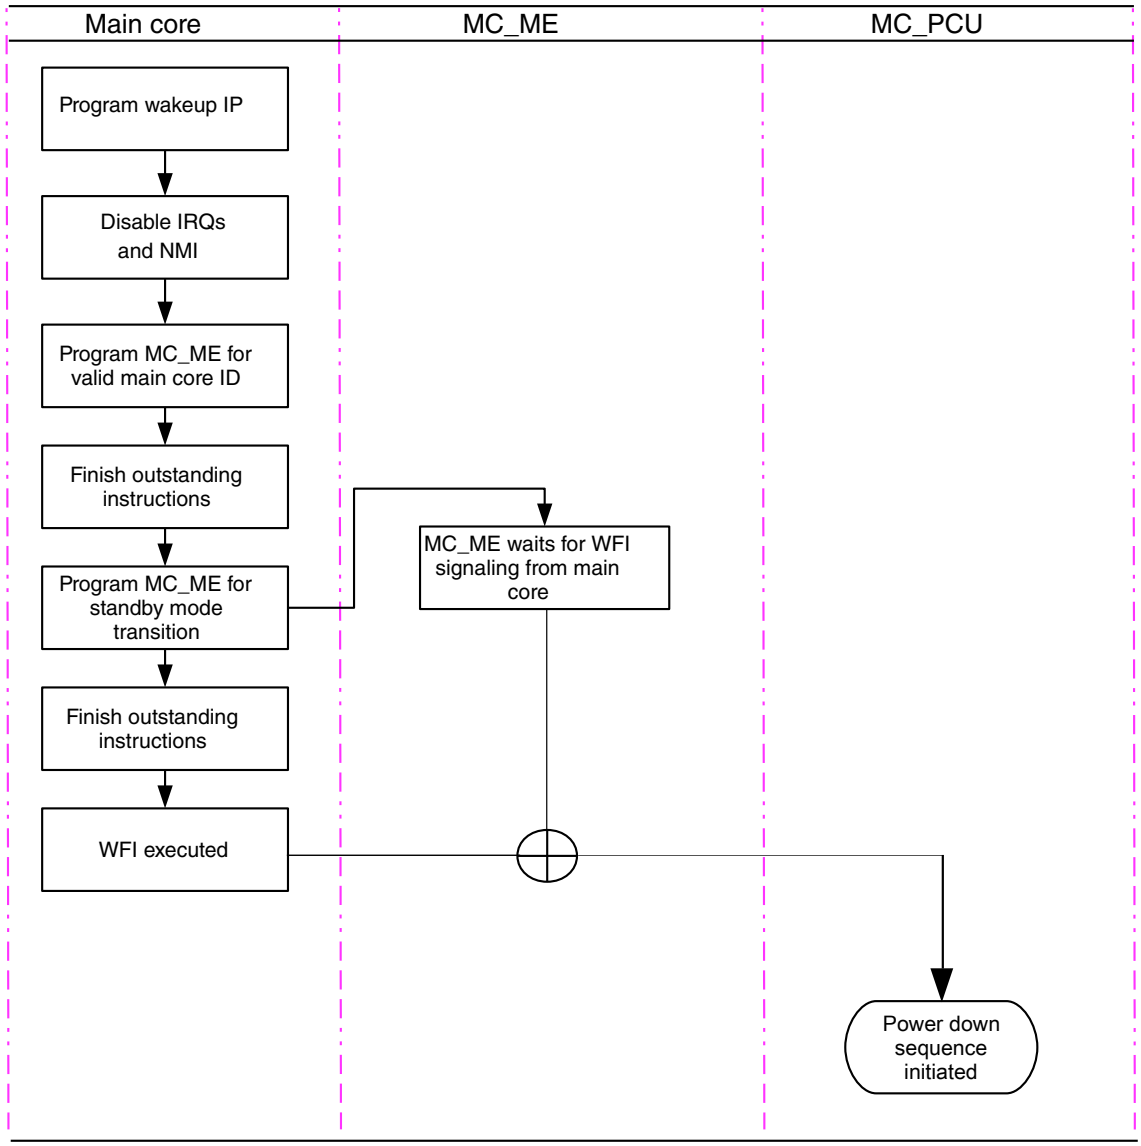

Figure 195. Standby entry sequence along with main core shutdown

NOTE

- MC_ME initiates the power sequence to MC_PCU. This enables the main core to remain inactive (WFI state) until it is reset and power-up again at standby exit.

46.7 MC_ME register descriptions

MC_ME implements set hardware processes that can be used by the software for changing the mode of operation for a partition. Following are the features of MC_ME registers:

- All registers are 32-bit wide.
- Only 32-bit read and write accesses are supported.
- Read/write accesses of less than 32 bits terminate with an error.
- Writes to read-only register fields in writable registers are ignored and do not provide an error message.

- Writes to read-only registers are aborted with an error message.

46.7.2 Control Key Register (CTL_KEY)

Offset

Register	Offset
CTL_KEY	0h

Function

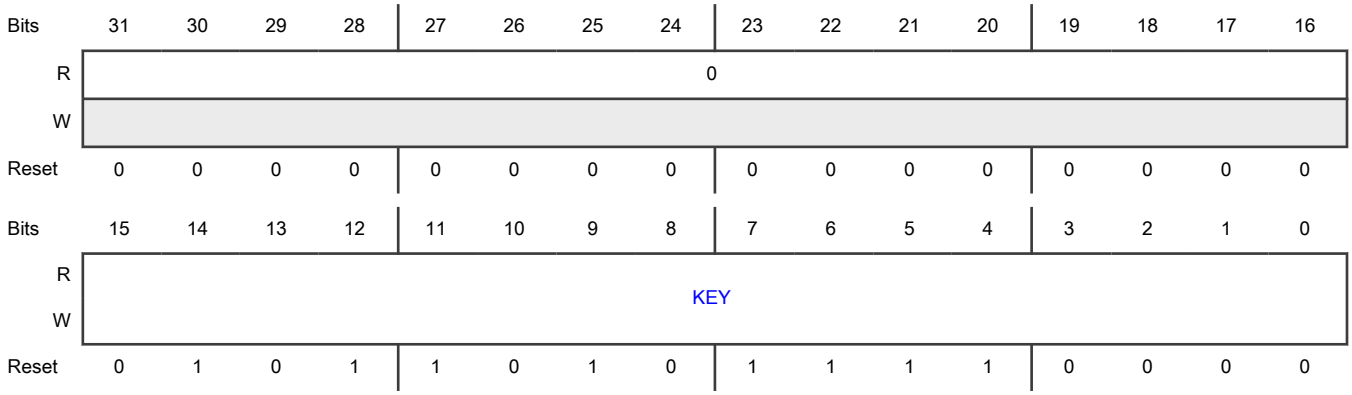
This register provides the mechanism to MC_ME for starting the hardware processes for the partition(s) and standby entry sequence. The hardware processes for partitions are triggered through the corresponding PRTNn_PCONF register. The mechanism to trigger the hardware processes of the respective partitions require two write operations: first time with key and second time with inverted key. The hexadecimal value of key is 0x5AF0 whereas for inverted key is 0xA50F.

For initiating a standby entry sequence, the MODE_CONF register is used for providing a standby entry request along with a valid key combination.

NOTE

Reads from this register return a valid key value to be written next.

Diagram



Fields

Field	Function
31-16 —	Reserved This field is reserved and read returns zeros.
15-0 KEY	Control key Key for starting the hardware processes. Writes with a value other than key or inverted key are ignored. Reads return bit inverted value corresponding to last write.

46.7.3 Mode Configuration Register (MODE_CONF)

Offset

Register	Offset
MODE_CONF	4h

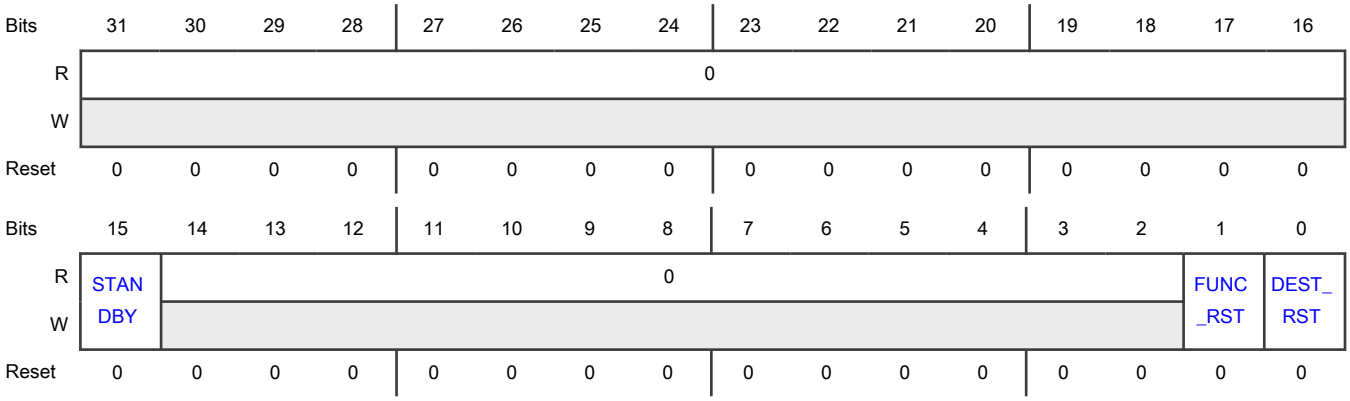
Function

This register is used for initiating a standby request or a reset event (destructive or functional) for the chip. The functional or destructive events are signaled to MC_RGM for further handling.

NOTE

Software must not enable mode entry if the value of multiple fields is 1 in the MODE_CONF register.

Diagram



Fields

Field	Function
31-16 —	Reserved This field is reserved and read returns zeros.
15 STANDBY	Standby request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a standby entry sequence request to MC_ME.
14-2 —	Reserved This field is reserved and read returns zeros.
1 FUNC_RST	Functional reset request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a functional reset event signaling to MC_RGM.
0 DEST_RST	Destructive reset request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a destructive reset event signaling to MC_RGM.

46.7.4 Mode Update Register (MODE_UPD)

Offset

Register	Offset
MODE_UPD	8h

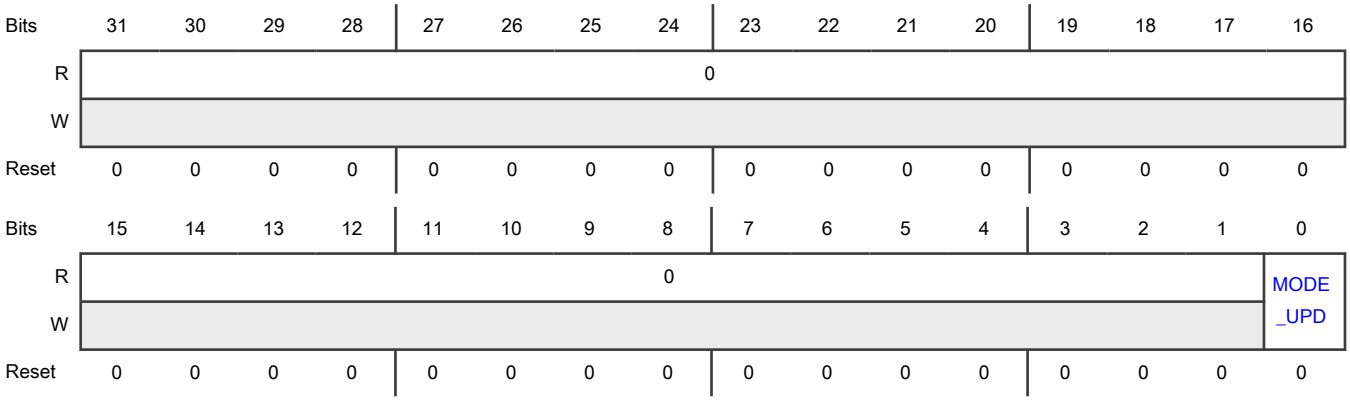
Function

This register is used for initiating a mode change. Mode change refers to initiating a standby request, or generating a destructive or functional reset event to MC_RGM. Setting mode update field to logic-1, along with programming MODE_CONF registers and then followed by a valid key combination will generate a mode transition request.

NOTE

The MODE_UPD register is implemented to make mode transition programming model the same as partition programming model. This is for future expansion inside MC_ME.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 MODE_UPD	Mode update Writing a logic-1 to this bit, followed by a valid key combination initiates a mode change as per the MODE_CONF register.

46.7.5 Mode Status Register (MODE_STAT)

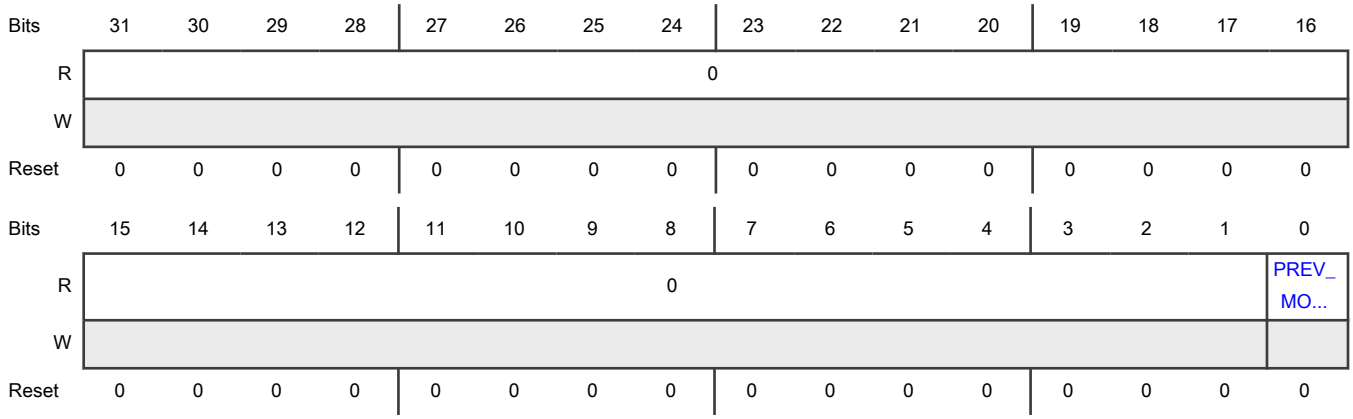
Offset

Register	Offset
MODE_STAT	Ch

Function

This register provides the status of the previous mode. In case of standby exit, if the reset event status register of MC_RGM are set, then contents of this register should be ignored.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 PREV_MODE	Previous mode This bit shows the status of the previous mode. 0b - The previous mode was reset (any reset). 1b - The previous mode was standby.

46.7.6 Main Core ID Register (MAIN_COREID)

Offset

Register	Offset
MAIN_COREID	10h

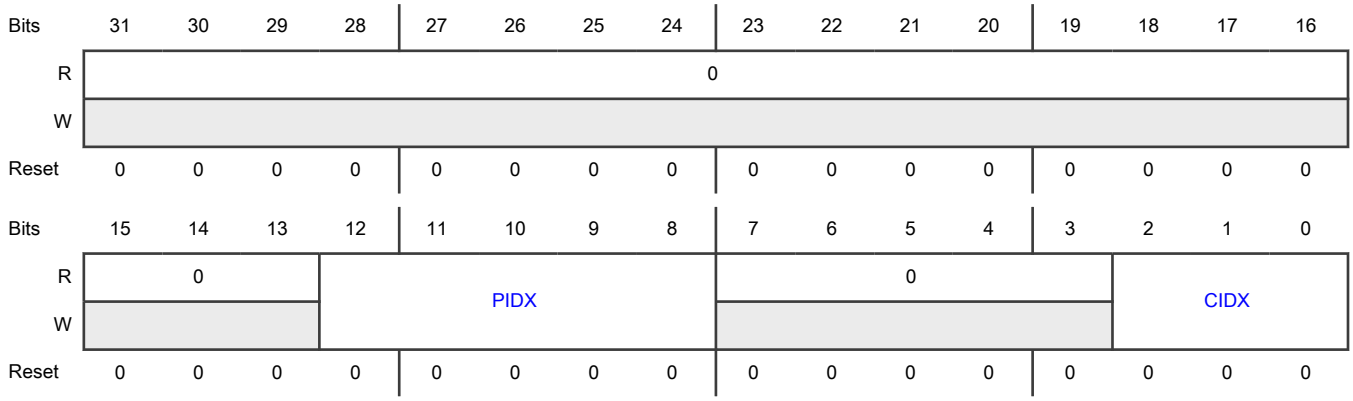
Function

This register provides the ID of the main core sequencing the operation for the standby sequence. Core ID is required for entering in the standby mode, and using this MC_ME locates the WFI instruction execution of the main core. The core ID in this register is specified by the partition index along with the core index.

NOTE

Before initiating a standby entry sequence, the contents of this register should point to the correct main core. Providing non-existing or incorrect core ID leads to unpredictable hardware behavior.

Diagram



Fields

Field	Function
31-13 —	Reserved This field is reserved and read returns zeros.
12-8 PIDX	Partition index Provides the partition index of the main core. Only values 0 - 2 can be written.
7-3 —	Reserved This field is reserved and read returns zeros.
2-0 CIDX	Core index Provides the core index of the main core inside the partition.

46.7.7 Partition 0 Process Configuration Register (PRTN0_PCONF)

Offset

Register	Offset
PRTN0_PCONF	100h

Function

This register provides a configuration for the hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_PCONF and PRTN0_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

0 PCE	Partition clock enable This bit controls whether the clock to IPs (other than core(s)) in the partition should be enabled or disabled. 0b - Disable the clock to IPs 1b - Enable the clock to IPs

46.7.8 Partition 0 Process Update Register (PRTN0_PUPD)

Offset

Register	Offset
PRTN0_PUPD	104h

Function

This register provides trigger signaling for the hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

46.7.10 Partition 0 Core Lockstep Control Register (PRTN0_CORE_LOCKSTEP)

Offset

Register	Offset
PRTN0_CORE_LOCKSTEP	10Ch

Function

This register provides the control for indicating a set of cores for lockstep execution in partition 0. Writes to this register immediately provide the corresponding bit to the described cores. No hardware process updates are required.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

46.7.13 Partition 0 COFB Set 0 Clock Enable Register (PRTN0_COFB0_CLKEN)

Offset

Register	Offset
PRTN0_COFB0_CLKEN	130h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 0. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

46.7.15 Partition 0 Core 0 Process Configuration Register (PRTN0_CORE0_PCONF)

Offset

Register	Offset
PRTN0_CORE0_PCONF	140h

Function

This register provides configurations for the Core 0 hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE0_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE0_PUPD and PRTN0_CORE0_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

Diagram

Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCE	Core 0 clock enable This bit controls whether the clock to Core 0 in partition 0 should be enabled or disabled. 0b - Disable the core clock 1b - Enable the core clock

46.7.16 Partition 0 Core 0 Process Update Register (PRTN0_CORE0_PUPD)

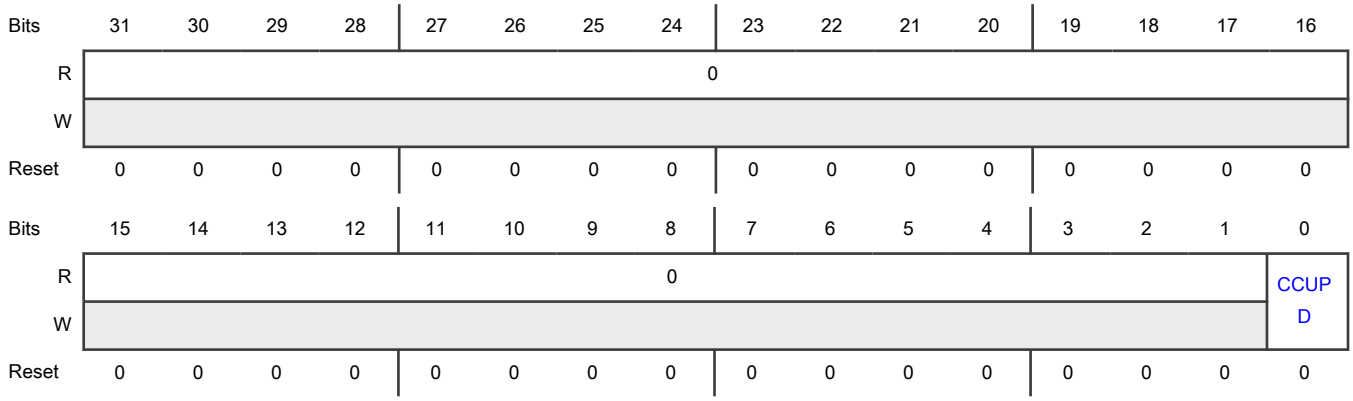
Offset

Register	Offset
PRTN0_CORE0_PUPD	144h

Function

This register provides trigger signaling for the core hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE0_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCUPD	Core 0 clock update This bit controls whether the hardware processes for enabling/disabling the clock to Core 0 in the partition 0 should be triggered or not. 0b - Do not trigger the hardware process 1b - Trigger the hardware process

46.7.17 Partition 0 Core 0 Status Register (PRTN0_CORE0_STAT)

Offset

Register	Offset
PRTN0_CORE0_STAT	148h

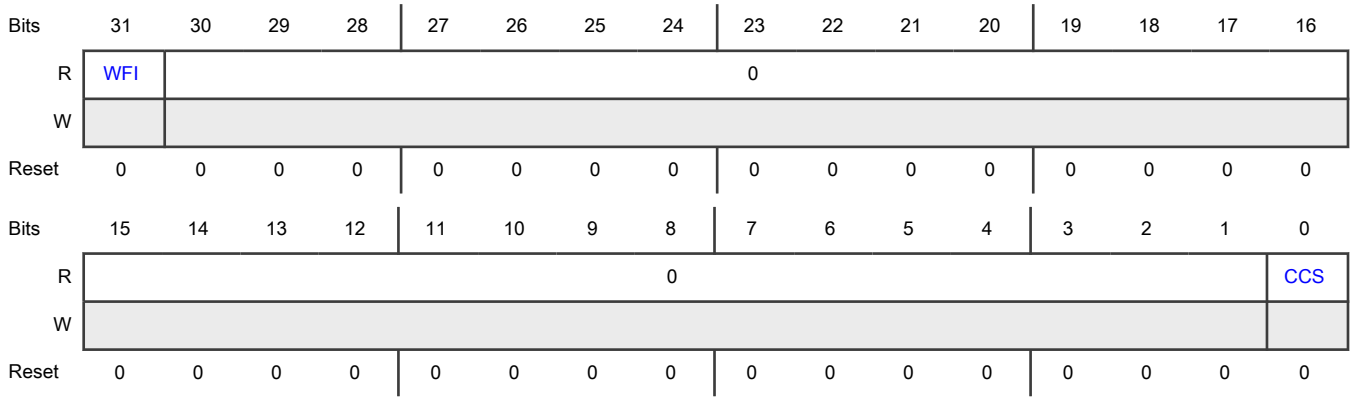
Function

This register provides the status corresponding to Core 0 in partition 0. The status signal corresponds to clock states and the WFI signal included from Core 0.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

Diagram



Fields

Field	Function
31 WFI	Wait for interrupt status This bit provides the WFI status approaching from Core 0 in partition 0. 0b - No WFI executed 1b - WFI executed
30-1 —	Reserved This field is reserved and read returns zeros.
0 CCS	Core 0 clock process status This bit provides the status of the clock corresponding to core clock enablement/disablement. 0b - Clock is inactive. 1b - Clock is active.

46.7.18 Partition 0 Core 0 Address Register (PRTN0_CORE0_ADDR)

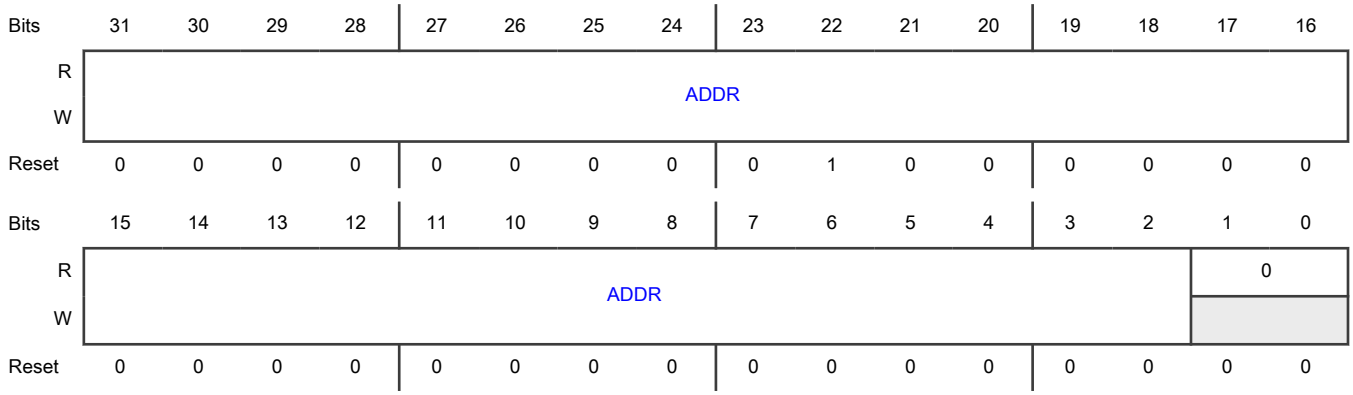
Offset

Register	Offset
PRTN0_CORE0_ADDR	14Ch

Function

This register contains the boot address for Core 0 in partition 0.

Diagram



Fields

Field	Function
31-2 ADDR	Address Core 0 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

46.7.19 Partition 0 Core 1 Process Configuration Register (PRTN0_CORE1_PCONF)

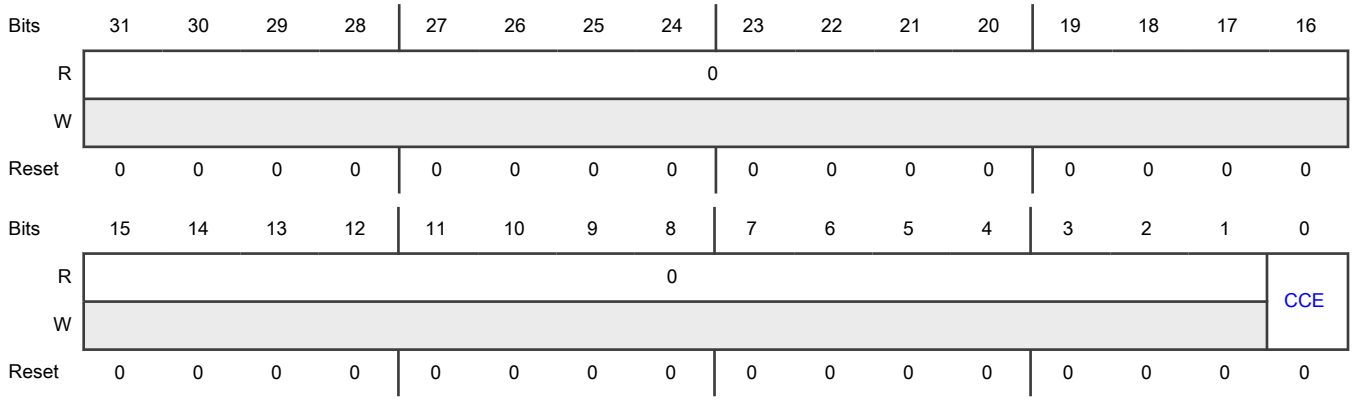
Offset

Register	Offset
PRTN0_CORE1_PCONF	160h

Function

This register provides configurations for the Core 1 hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE1_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE1_PUPD and PRTN0_CORE1_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCE	Core 1 clock enable This bit controls whether the clock to Core 1 in partition 0 should be enabled or disabled. 0b - Disable the core clock 1b - Enable the core clock

46.7.20 Partition 0 Core 1 Process Update Register (PRTN0_CORE1_PUPD)

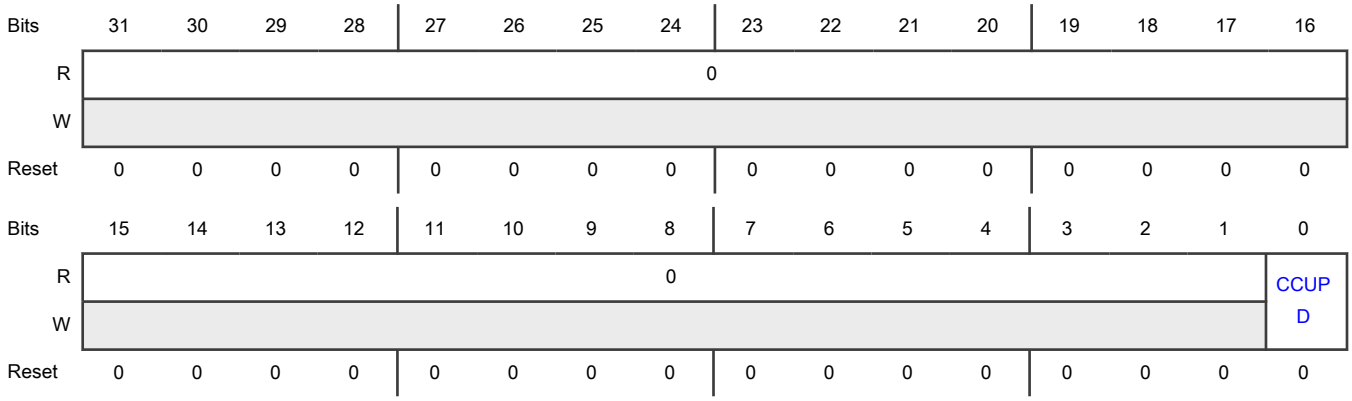
Offset

Register	Offset
PRTN0_CORE1_PUPD	164h

Function

This register provides trigger signaling for the core hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE1_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCUPD	Core 1 clock update This bit controls whether the hardware processes for enabling/disabling the clock to Core 1 in the partition 0 should be triggered or not. 0b - Do not trigger the hardware process 1b - Trigger the hardware process

46.7.21 Partition 0 Core 1 Status Register (PRTN0_CORE1_STAT)

Offset

Register	Offset
PRTN0_CORE1_STAT	168h

Function

This register provides the status corresponding to Core 1 in partition 0. The status signal corresponds to clock states and the WFI signal included from Core 1.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

30-1 —	Reserved This field is reserved and read returns zeros.
0 CCS	Core 1 clock process status This bit provides the status of the clock corresponding to core clock enablement/disablement. 0b - Clock is inactive. 1b - Clock is active.

46.7.22 Partition 0 Core 1 Address Register (PRTN0_CORE1_ADDR)

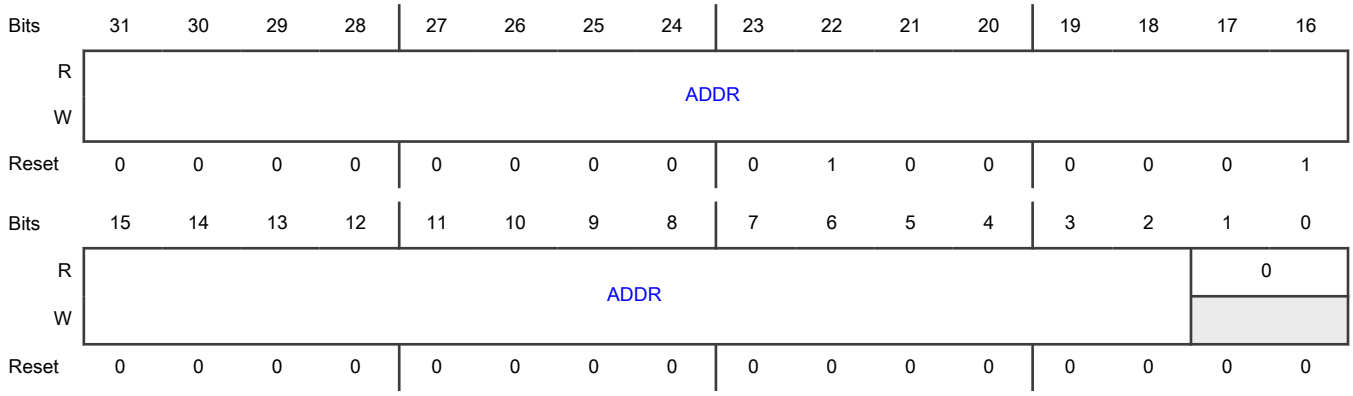
Offset

Register	Offset
PRTN0_CORE1_ADDR	16Ch

Function

This register contains the boot address for Core 1 in partition 0.

Diagram



Fields

Field	Function
31-2 ADDR	Address Core 1 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

46.7.23 Partition 0 Core 2 Status Register (PRTN0_CORE2_STAT)

Offset

Register	Offset
PRTN0_CORE2_STAT	188h

Function

This register provides the status corresponding to Core 2 in partition 0. The status signal corresponds to clock states and the WFI signal included from Core 2.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

Field	Function
31 WFI	Wait for interrupt status This bit provides the WFI status approaching from Core 4 in partition 0. 0b - No WFI executed 1b - WFI executed
30-1 —	Reserved This field is reserved and read returns zeros.
0 CCS	Core 4 clock process status This bit provides the status of the clock corresponding to core clock enablement/disablement. 0b - Clock is inactive. 1b - Clock is active.

46.7.32 Partition 0 Core 4 Address Register (PRTN0_CORE4_ADDR)

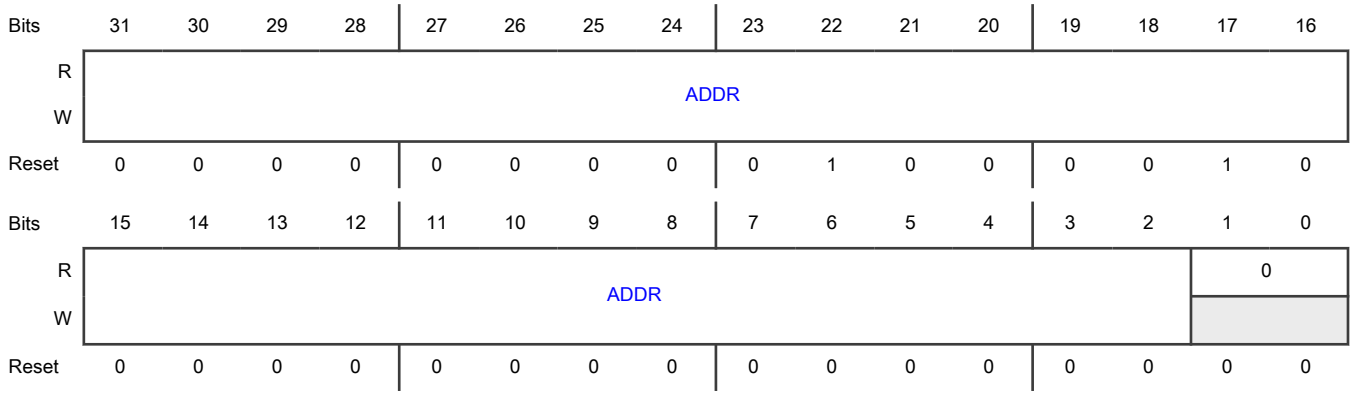
Offset

Register	Offset
PRTN0_CORE4_ADDR	1CCh

Function

This register contains the boot address for Core 4 in partition 0.

Diagram



Fields

Field	Function
31-2 ADDR	Address Core 4 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

46.7.33 Partition 0 Core 5 Process Configuration Register (PRTN0_CORE5_PCONF)

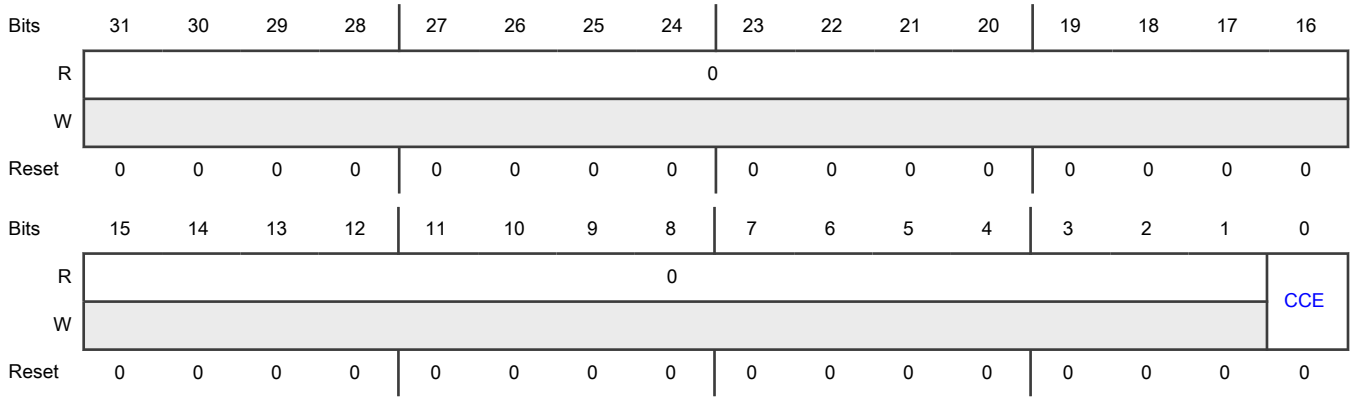
Offset

Register	Offset
PRTN0_CORE5_PCONF	1E0h

Function

This register provides configurations for the Core 5 hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE5_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE5_PUPD and PRTN0_CORE5_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCE	Core 5 clock enable This bit controls whether the clock to Core 5 in partition 0 should be enabled or disabled. 0b - Disable the core clock 1b - Enable the core clock

46.7.34 Partition 0 Core 5 Process Update Register (PRTN0_CORE5_PUPD)

Offset

Register	Offset
PRTN0_CORE5_PUPD	1E4h

Function

This register provides trigger signaling for the core hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE5_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.

Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCUPD	Core 5 clock update This bit controls whether the hardware processes for enabling/disabling the clock to Core 5 in the partition 0 should be triggered or not. 0b - Do not trigger the hardware process 1b - Trigger the hardware process

46.7.35 Partition 0 Core 5 Status Register (PRTN0_CORE5_STAT)

Offset

Register	Offset
PRTN0_CORE5_STAT	1E8h

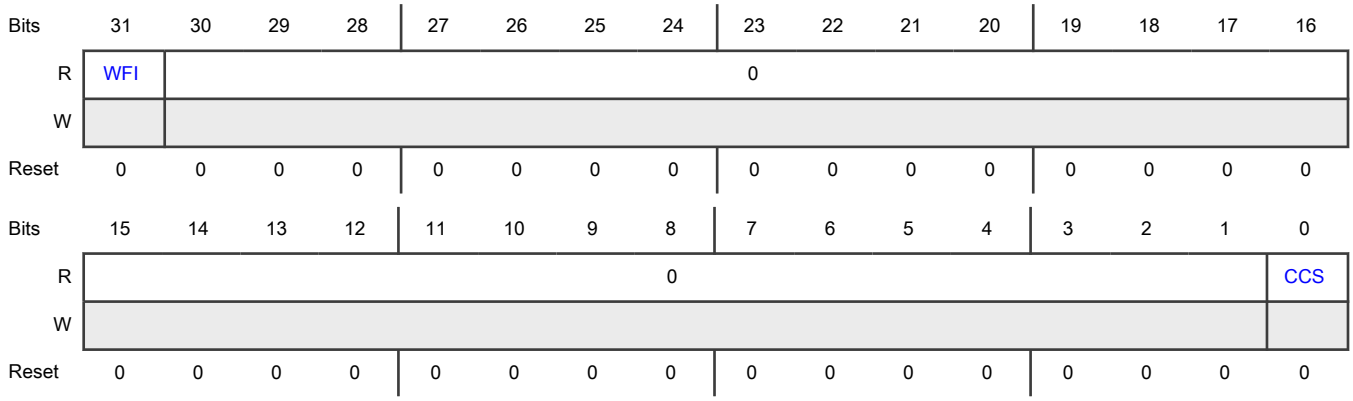
Function

This register provides the status corresponding to Core 5 in partition 0. The status signal corresponds to clock states and the WFI signal included from Core 5.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

Diagram



Fields

Field	Function
31 WFI	Wait for interrupt status This bit provides the WFI status approaching from Core 5 in partition 0. 0b - No WFI executed 1b - WFI executed
30-1 —	Reserved This field is reserved and read returns zeros.
0 CCS	Core 5 clock process status This bit provides the status of the clock corresponding to core clock enablement/disablement. 0b - Clock is inactive. 1b - Clock is active.

46.7.36 Partition 0 Core 5 Address Register (PRTN0_CORE5_ADDR)

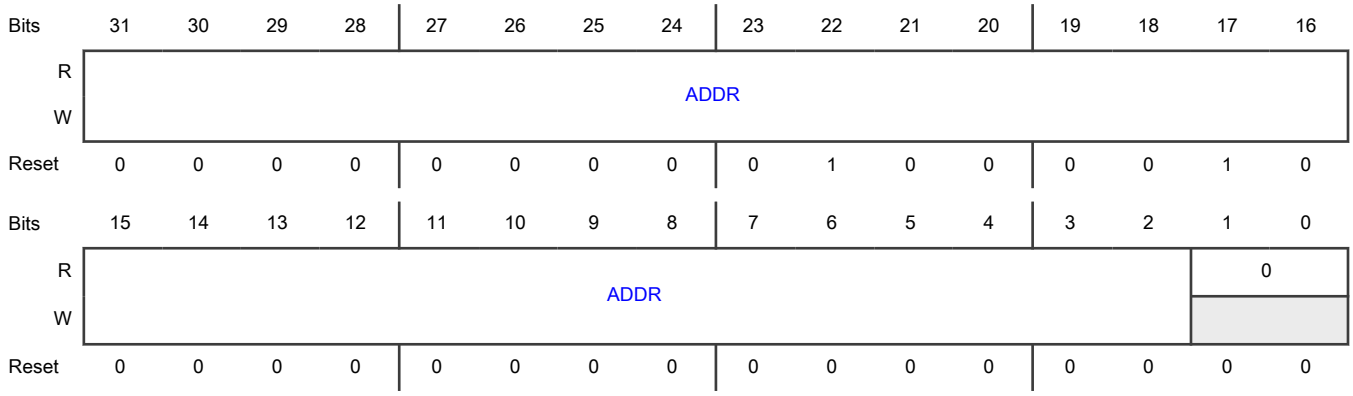
Offset

Register	Offset
PRTN0_CORE5_ADDR	1ECh

Function

This register contains the boot address for Core 5 in partition 0.

Diagram



Fields

Field	Function
31-2 ADDR	Address Core 5 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

46.7.37 Partition 1 Process Configuration Register (PRTN1_PCONF)

Offset

Register	Offset
PRTN1_PCONF	300h

Function

This register provides a configuration for the hardware processes corresponding to partition 1. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN1_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN1_PCONF and PRTN1_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

0 PCE	Partition clock enable This bit controls whether the clock to IPs (other than core(s)) in the partition should be enabled or disabled. 0b - Disable the clock to IPs 1b - Enable the clock to IPs

46.7.38 Partition 1 Process Update Register (PRTN1_PUPD)

Offset

Register	Offset
PRTN1_PUPD	304h

Function

This register provides trigger signaling for the hardware processes corresponding to partition 1. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN1_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

0 PCS	Partition clock status This bit provides the status of the clock to partition. 0b - Clock is inactive 1b - Clock is active

46.7.40 Partition 1 COFB Set 0 Clock Status Register (PRTN1_COFB0_STAT)

Offset

Register	Offset
PRTN1_COFB0_STAT	310h

Function

This register provides the status of set 0 of COFBs inside partition 1.

NOTE

The reset value of this register can vary depending on the availability of active clock pulses inside partition 1.

Offset

Register	Offset
PRTN1_COFB3_STAT	31Ch

Function

This register provides the status of set 3 of COFBs inside partition 1.

NOTE

The reset value of this register can vary depending on the availability of active clock pulses inside partition 1.

46.7.44 Partition 1 COFB Set 0 Clock Enable Register (PRTN1_COFB0_CLKEN)

Offset

Register	Offset
PRTN1_COFB0_CLKEN	330h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 1. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

Field	Function
	0b - Clock is turned off. 1b - Clock is turned on.

46.7.48 Partition 2 Process Configuration Register (PRTN2_PCONF)

Offset

Register	Offset
PRTN2_PCONF	500h

Function

This register provides a configuration for the hardware processes corresponding to partition 2. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN2_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN2_PCONF and PRTN2_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

3 —	Reserved This field is reserved and read returns zeros.
2 —	Reserved This field is reserved and read returns zeros.
1 —	Reserved This field is reserved and read returns zeros.
0 PCE	Partition clock enable This bit controls whether the clock to IPs (other than core(s)) in the partition should be enabled or disabled. 0b - Disable the clock to IPs 1b - Enable the clock to IPs

46.7.49 Partition 2 Process Update Register (PRTN2_PUPD)

Offset

Register	Offset
PRTN2_PUPD	504h

Function

This register provides trigger signaling for the hardware processes corresponding to partition 2. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN2_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

Diagram

1 —	Reserved This field is reserved and read returns zeros.
0 PCUD	Partition clock update This bit controls whether the hardware processes for enabling/disabling the clock to IPs (other than core(s)) in the partition should be triggered or not. 0b - Do not trigger the hardware process 1b - Trigger the hardware process

46.7.50 Partition 2 Status Register (PRTN2_STAT)

Offset

Register	Offset
PRTN2_STAT	508h

Function

This register provides the current status of the control signals from the partition 2.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

46.7.55 Partition 2 COFB Set 0 Clock Enable Register (PRTN2_COFB0_CLKEN)

Offset

Register	Offset
PRTN2_COFB0_CLKEN	530h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 2. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

46.8 Glossary

WFI Wait for interrupt

COFB Collection of functional blocks also referred as number of peripherals

Chapter 47
Power Control Unit (MC_PCU)

47.1 Introduction

The power control unit (MC_PCU) is used for initiating a Standby mode entry that reduces the overall chip power consumption. Power can be saved by disconnecting parts of the chip from the power supply. The blocks inside the chip are grouped into multiple parts having this capability, which are called "power domains".

When a power domain is disconnected from the supply, the power consumption is reduced to zero in that domain. Any status information, such as, power domain is lost. When you reconnect a power domain to the supply voltage, the domain draws an increased current until the power domain reaches its operational voltage. Maximum power saving is achieved by entering the Standby mode.

After the MC_RGM asserts a standby entry request, MC_PCU initiates the power sequence, which is non-retractable and includes the handshake with the chip power management controller. The power-up/down sequences are handled by FSMs to ensure a smooth and safe transition into and out of the Standby mode. Exiting the Standby mode can only be done through a system wakeup event, power-on reset, destructive reset, or a functional reset.

47.2 Power sequence FSM

MC_PCU implements an FSM to initiate the power sequencing of the Standby mode entry/exit sequence for the chip.

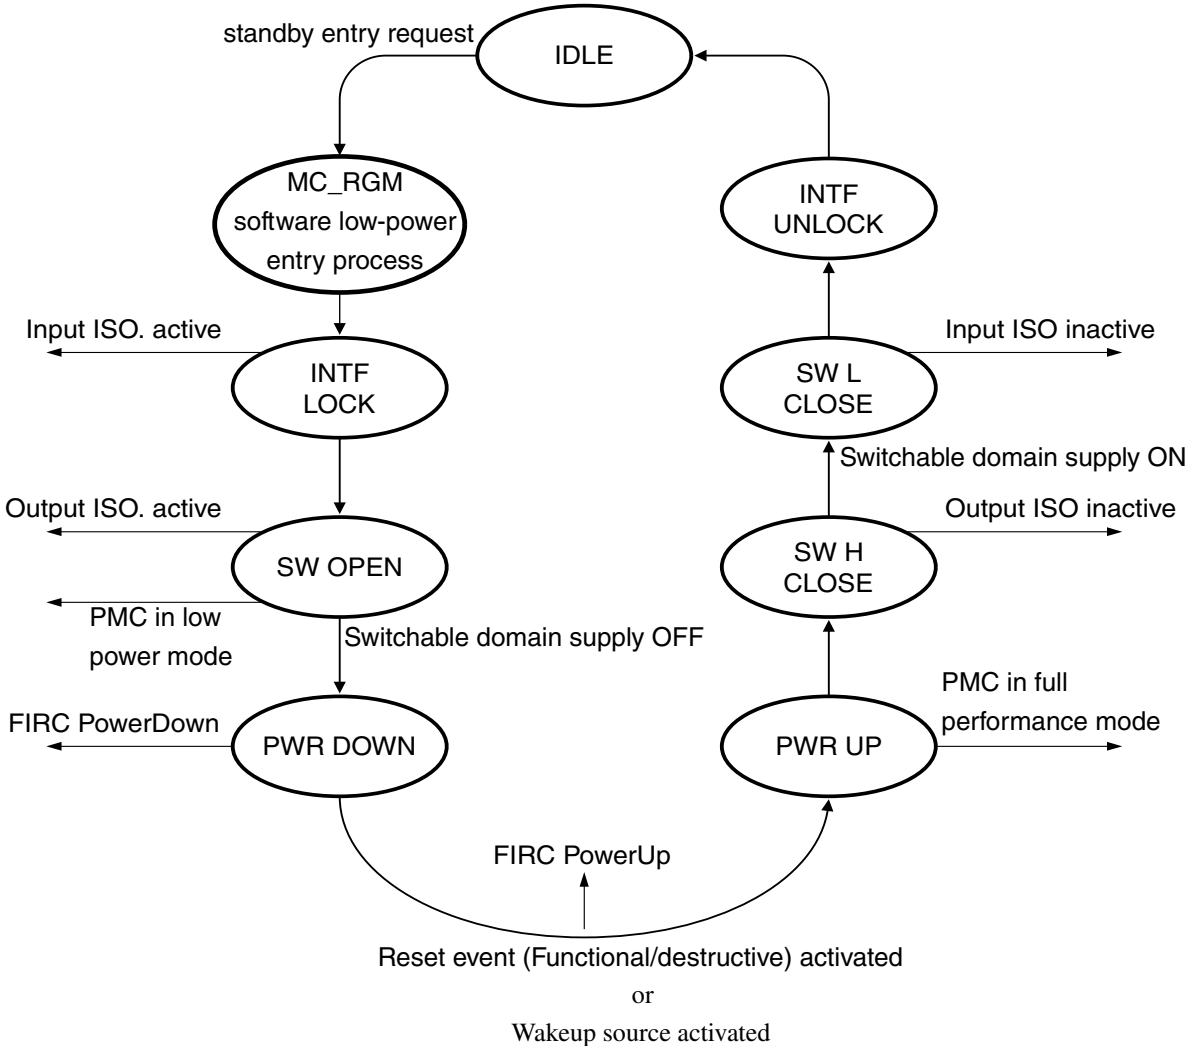

Figure 196. MC_PCU FSM

NOTE

When destructive reset is asserted from MC_RGM, MC_PCU FSM moves to the IDLE state immediately. Indication of this is not shown in the above figure.

Table 264. MC_PCU FSM transition description

State	Name	Exit condition	Signal controlled	Signal monitored

FSM Finite state machine

Chapter 48
Wakeup Unit (WKPU)

48.1 Chip-specific WKPU information

48.1.1 WKPU configuration on the chip

WKPU provides the following features:

- A configurable, low-power wake-up capability to the chip from multiple configurable asynchronous wake-up events.
- Support for four internal and minimum 59 external source depending on the chip, that can generate interrupts or wake-up events.
- Support for an NMI input.

Table 265. WKPU configuration on the chip

Number of sources, interrupts, and vectors	S32K344/ S32K324/ S32K314/ S32K342/ S32K341/ S32K322/ S32K312/ S32K311/ S32K310	S32K388/ S32K389/ S32K358/ S32K348/ S32K338/ S32K328	Description
NMI sources	1	1	Single NMI pin routed to all application cores
Internal wake-up sources[1]	4	4	• SWT_0 wake-up, RTC-API wake-up • RTC timeout • Analog comparator round robin wake-up (from LPCMP_0, 1, and 2 round robin wake-up)[2] • RTI wake-up
External wake-up sources	60	67 [3]	Minimum 59 GPIO pins (WKPU[0]-WKPU[59])[4] support the wake-up functionality. See the IOMUX file attached to this document for details.
Glitch filters for external interrupts	60	67	Glitch filter on each external wake-up source
External interrupt vectors	8	8	—

1. Internal wakeup sources have only positive polarity, therefore, must not be configured for negedge triggered functionality.
2. Both wake-up sources 0 (RTC-API) and 2 (CMP_*x* trigger mode wake-up) use RTC-API wake-up, with Trigger mode having a higher priority. This means, if you configure LPCMP_*x*.RRCR0[ERR_EN] for either of the comparators, the RTC_API wake-up is used only for the CMP_*x* trigger mode operation. The RTC-API wake-up does not cause wake-up from Standby mode in this scenario.
3. Some of external sources are sharing the same WKPU channels. Please see DCM_GPR chapter to select one from multiple external sources.
4. For S32K312, WKPU[34] is reserved. S32K311 supports WKPU[0]-WKPU[29], WKPU[31]-WKPU[33]

All of the aforementioned wake-up sources can be enabled or disabled. Also, you can configure these wake-up sources, by using WKPU configuration registers, to provide wake-up on rising or falling events. See the WKPU register memory map for details.

NOTE

You must use SIUL2 to perform WKPU pin configurations (PUE, PUS, and IBE). For this, you must first configure SIUL2.MSCR[IBE] for the corresponding pin. This chip does not support WKPU-provided pin configurations; it supports only bypass control.

Two kinds of BYPASS connectivity for alternate glitch filters

Below figure is related to the BYPASS functionality of the Analog glitch filters associated with external wakeup pins.

48.1.2 WKPU register fields and their applicability

Table 266. WKPU register fields and applicability

Register	Field	Chips where applicable
NSR	NIF1	S32K324, S32K322
NSR	NOVF1	S32K324, S32K322
NSR	NIF3, NOVF3	S32K388/S32K389
NCR	NLOCK1	S32K324, S32K322
NCR	NDSS1	S32K324, S32K322
NCR	NWRE1	S32K324, S32K322
NCR	NREE1	S32K324, S32K322
NCR	NFEE1	S32K324, S32K322
NCR	NFE1	S32K324, S32K322
NCR	NLOCK3, NDSS3, NWRE3, NREE3, NFEE3, NFE3	S32K388/S32K389

48.1.3 WKPU NMI configuration

WKPU supports one external source that can cause non-maskable interrupts to on-chip cores and wake-up events to the system.

The following figure shows applicable cores, some family chips may not have cores Cortex-M7_1, Cortex-M7_2 or Coretex-M7_3. In case of a wake-up event (internal or external), WKPU initiates the recovery of the chip and feeds an interrupt to the core(s) depending on the configuration. The sections that follow provide details related to the associated configurations.

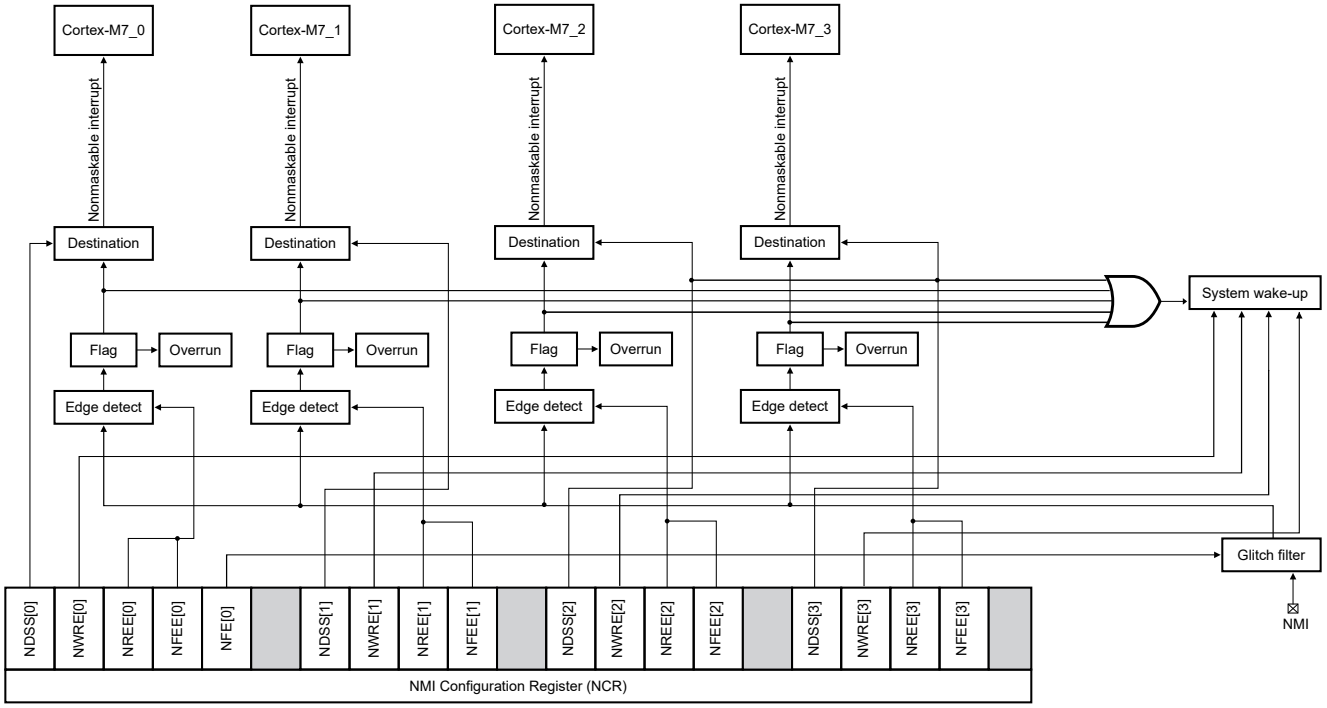

Figure 197. WKPU NMI configuration

48.1.4 WKPU wake-up source connectivity

WKPU allows the external NMI pin to assert the core NMIs on the chip. NMI supports NSR's status and overrun flags. This is what you could do using NCR:

- Control the NMI destination interrupt by configuring NCR[NDSS].
- Control the rising edge, falling edge, or either of the edge reactions to the NMI pin by using bits 2:0 of NCR[NFEE] and NCR[NREE]. The enabling of these edge reactions to the NMI pin is independent of each core.

WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

The following figure shows routing of external wake-up events or interrupts with WKPU and the system interrupt controller.

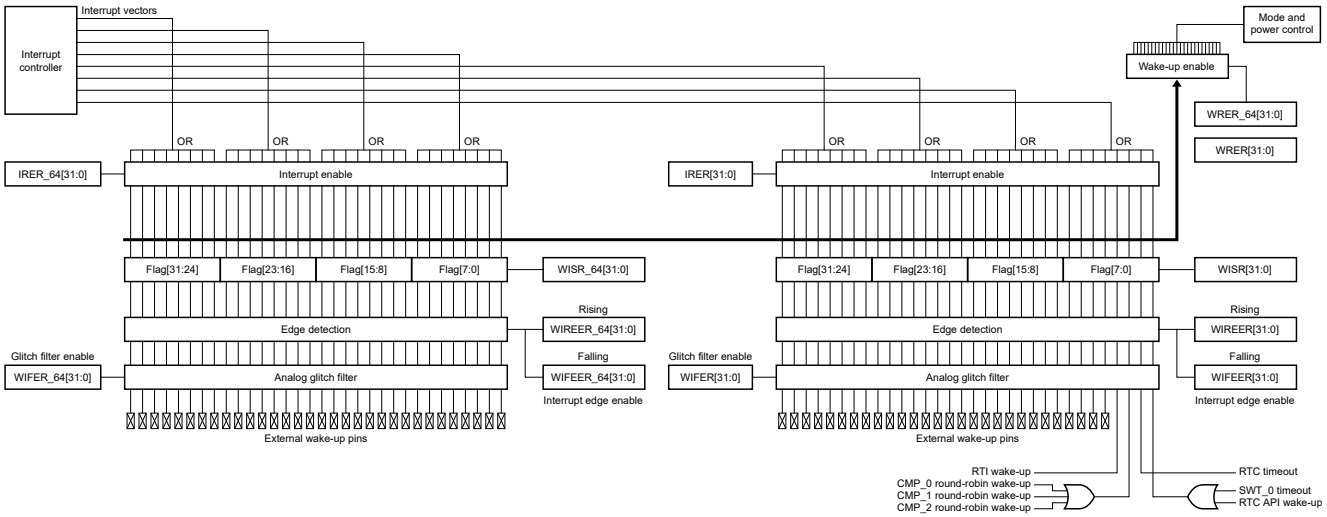

Figure 198. WKPU wake-up source connectivity

This is the wake-up source mapping to WKPU:

- Wake-up source 0 : SWT_0 timeout, RTC-API API wake-up
- Wake-up source 1 : RTC-API RTC timeout
- Wake-up source 2 : Round robin wake-up interrupt (Trigger mode interrupt) from LPCMP_0, LPCMP_1, or LPCMP_2
- Wake-up source 3 : RTI wake-up
- Wake-up source 4 : Wake-up source minimum 59-external pin wake-up sources, WKPU[0]-WKPU[59]

If you configure any or all of the LPCMP_*x*.RRCR0[RR_EN] fields to be active, the corresponding CMP_*x* pins must be dedicated for the CMP_*x* operation. In case you are not using any of the CMPs, you can use SIUL2.MSCR*x*[SSS] to configure the pins for digital functionalities.

NOTE

You must enable WKPU (by using MC_ME.PRTN*x*_COFB*y*_CLKEN) before entering any of the chip's low-power modes.

48.2 Overview

The WKPU supports 64 external sources that can generate interrupts or wakeup events and 0 external source(s) that can cause non-maskable interrupt request(s) or wakeup event(s). In addition, it combines its wakeup events with those generated from other wakeup sources to supply a single wakeup to the system.

48.2.1 Block diagram

The block diagram of WKPU and its interfaces to other system components is shown below.

NOTE

The signal widths in the following diagram might not depict this device's particular configuration. See chip-specific WKPU for more information.

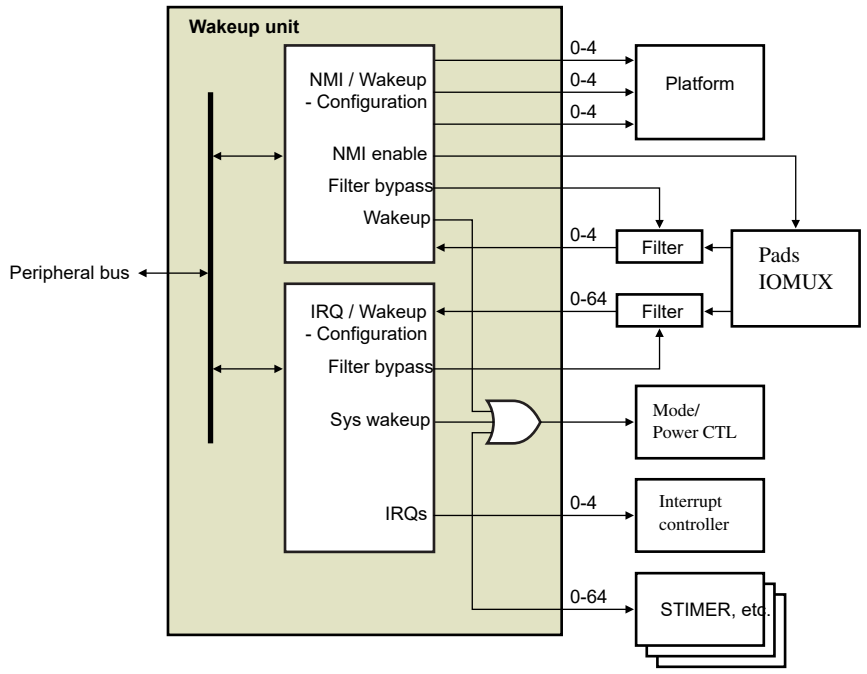

Figure 199. WKPU and connected system components

48.2.2 Features

The WKPU supports these features:

- Non-maskable interrupt support with:
  - 4 NMI sources
  - 4 analog glitch filters
  - Independent interrupt destination for each core:
    - Non-maskable interrupt
    - Critical interrupt
  - Active (rise/fall) edge selection control for events
  - Configurable system wakeup triggering from NMI sources
- External wakeup/interrupt support with:
  - One System interrupt vector for interrupt sources
  - 64 analog glitch filters
  - Independent interrupt mask
  - Edge detection
  - Configurable system wakeup triggering from all interrupt sources

48.3 Functional description

This section provides functional description of WKPU.

48.3.1 Non-maskable interrupts

The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event, although it creates an overrun condition.

Each NMI passes through a bypassable analog glitch filter.

NOTE

Glitch filter control and pad configuration should be performed when NMI is disabled, to avoid erroneous triggering by glitches caused by the configuration process itself.

NOTE

The figure below represents a generic configuration and might not represent this particular device's configuration. See the chip-specific information for details on this chip's WKPU.

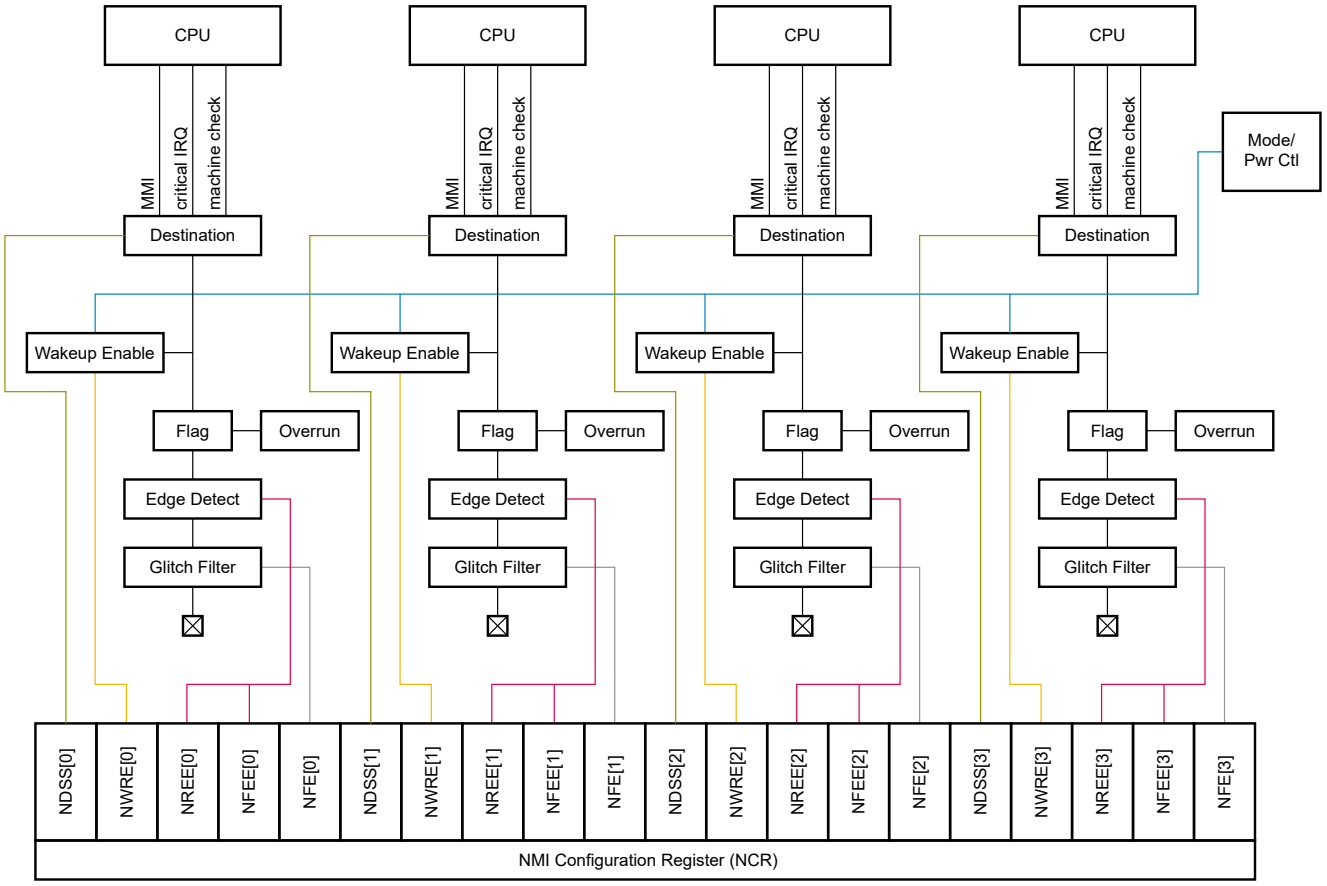

Figure 200. NMI pad diagram

48.3.1.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the NCR laid out to contain all configuration bits for a given NMI in a single byte (see NMI Configuration Register (NCR)). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NCR[NREEn] and NCR[NFEEn] bits.

NOTE

After reset, NREE and NFEE are set to '0'; therefore, the NMI functionality is disabled after reset and must be enabled explicitly by software.

After a pad's NMI functionality is enabled, the pad cannot be reconfigured to override or disable the NMI. See the chip-specific WKPU information for details of NMI implementation.

The NMI destination interrupt is controlled by the user through the configuration of the NCR[NDSSn] bits. See NMI Configuration Register (NCR) for details.

Each NMI supports a status flag and an overrun flag, which are located in the NSR register (see NMI Status Flag Register (NSR)). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (that is, status flag has not been cleared).

NOTE

The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt is not cleared.

During an NMI ISR, on wakeup of the chip from an NMI, any writes to the ECC-protected memory must have the correct ECC.

48.3.2 Clocking

This module has no clocking considerations.

The WKPU has ipg_clk and ipg_clk_s as input clocks having same clock frequency for register configuration and internal logic.

48.3.3 Interrupts

The WKPU supports 4 interrupt vectors to the interrupt controller of the chip. Each interrupt vector can support up to the number of external interrupt sources from the device pads, with the total across all vectors being equal to the number of external interrupt sources. Each external interrupt source is assigned to exactly one interrupt vector. The interrupt vector assignment is sequential so that one interrupt vector is for external interrupt sources 0 through N-1, the next is for N through N+M-1, and so forth.

See the following figure for an overview of the external interrupt implementation, showing an example of four interrupt vectors with eight external interrupt sources each.

NOTE

The figure below shows a generic representation of WKPU. See the chip-specific WKPU information for details on how this device's configuration might differ from this figure.

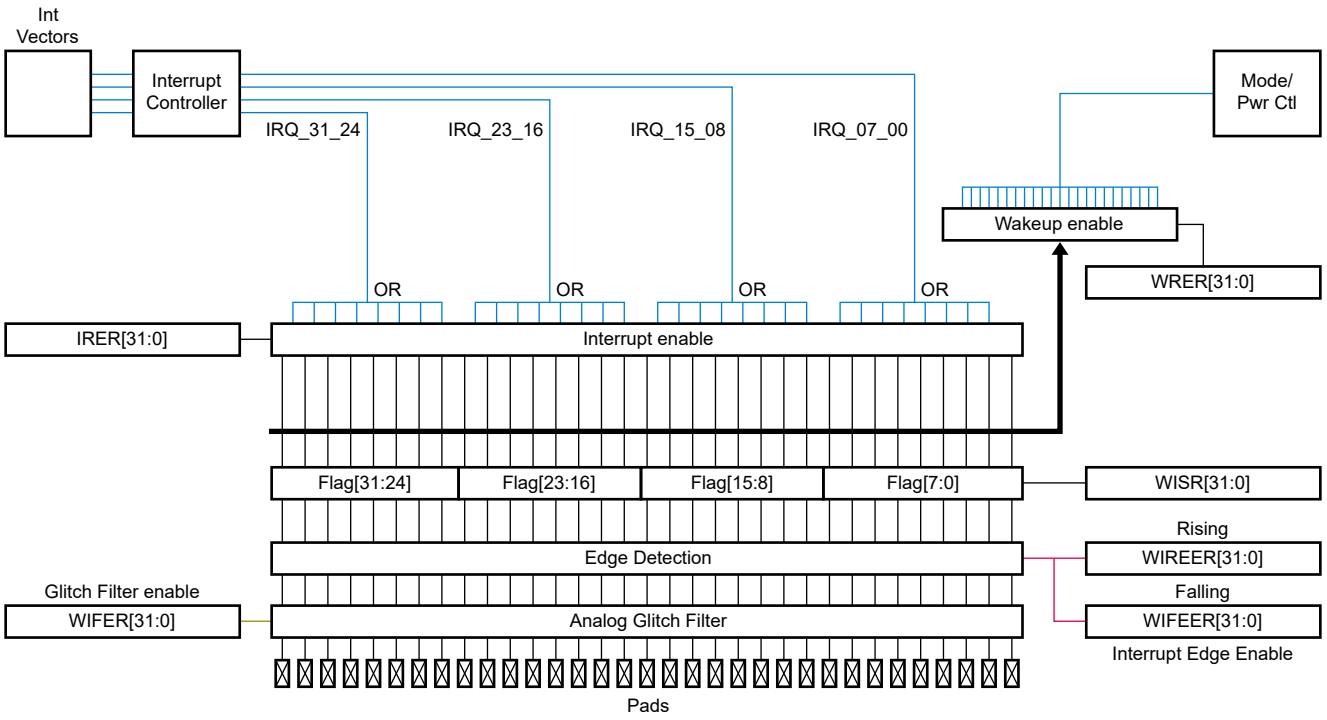

Figure 201. External interrupt pad diagram

All of the external interrupt pads within a single group have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is set based on the platform and the interrupt controller's priority levels, but the allocation of pads to each group of interrupts can be independently configured by the chip.

External interrupt lines have a digital glitch filter applied to them.

48.3.3.1 External interrupt management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled-up register (Interrupt Request Enable Register (IRER)). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active.

NOTE

Writing a '0' to both IREE[x] and IFEE[x] disables the external interrupt functionality for that pad completely (that is, no system wakeup or interrupt is generated on any activity of that pad).

The active IRQ edge is controlled by users through the configuration of the registers WIREER and WIFEER.

Each external interrupt supports an individual flag, which is held in the flag register, WISR. This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

48.3.4 External Signals

This module has no external signals.

48.4 Initialization

This section discusses initialization for the following features:

- Glitch filter and pad configuration

- Non-maskable interrupts

48.4.1 Glitch filter and pad configuration

Glitch filter control and pad configuration should be performed when the NMI is disabled. This is to avoid erroneous triggering by glitches caused by the configuration process.

When enabling the glitch filter, do not enable the rising-/falling-edge events bits, i.e., the NCR[NREE], NCR[NFEE], NCR[RREE], and NCR[RFEE] bits in the same register write.

48.4.2 Non-maskable interrupts

If the IBE of NMI is tied off to 1, no false interrupt is expected.

48.5 WKPU memory map and registers

48.5.1 WKPU register descriptions

This section provides a detailed description of all the registers accessible in the WKPU module.

NOTE

Reserved registers read as zero and writes have no effect. A transfer error is generated when trying to access a completely reserved register space. The field length of external pad control registers depends on the number of WKPU channels implemented in a chip.

48.5.1.1 WKPU memory map

WKPU base address: 402B_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	NMI Status Flag Register (NSR)	32	RW	0000_0000h

6 NOVF3	NMI Overrun Status Flag 3 This flag can be cleared only by writing 1. Writing 0 has no effect. It will be a copy of the current NIF3 value whenever an NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. If enabled (NREE3] or NFEE3] set), NOVF3] causes an interrupt request. 0b - No overrun has occurred on NMI input 3 1b - An overrun has occurred on NMI input 3
5-0 —	Reserved

48.5.1.3 NMI Configuration Register (NCR)

Offset

Register	Offset
NCR	8h

Function

This register holds the configuration bits for the non-maskable interrupt settings.

NOTE

- This register is accessible by 8-, 16-, and 32-bit read/write operations.
- Writing 0 to both NREE[*n*] and NFEE[*n*] disables the NMI functionality completely (that is, no non-maskable interrupt is generated on any pad activity).

Access: User read/write

48.5.1.4 Wakeup/Interrupt Status Flag Register (WISR)

Offset

Register	Offset
WISR	14h

Function

This register holds the wakeup/interrupt flags.

NOTE

- This register is accessible only by 32-bit read/write operations.
- Status bits associated with on-chip wakeup sources are located at the left of the external wakeup/interrupt status bits and are read-only. The wakeup for these sources must be configured and cleared at the on-chip wakeup source. Also, the configuration registers for the external interrupts/wakeups do not have corresponding bits.

Access: User read/write

48.6 Glossary

NMI Non-maskable interrupts

Chapter 49
Safety Overview

49.1 Introduction

This chip family is developed following the ISO 26262 standards, with derivatives targeting to be operable in a system that fulfills the requirements of the ASIL D or ASIL B safety integrity levels. The S32K388, S32K389, and S32K358 can target an ASIL B safety integrity level with one portion of the chip, while targeting an ASIL D safety integrity level with another portion.

Table 267. ASIL levels

Chip	ASIL level
S32K388, S32K389, S32K358, S32K348, S32K344, S32K342, S32K341	D and B
S32K338, S32K328, S32K324, S32K314, S32K322, S32K312, S32K311, S32K310	B

The ASIL level targets the safety processing, which means the software functions are executed as intended:

1. Read instructions from memory.
2. Execute instructions.
3. Read data from memory.
4. Process data.
5. Write back the result data into memory.

Some elements of the safety concept are based on the assumption that the chip is connected to an external SBC or PMIC. The SBC or PMIC performs observations and control functionalities that are essential to fulfill some related functional safety requirements. If you do not use an SBC or PMIC, you must ensure that your S32K-family chip provides an equivalent functionality that properly manages the corresponding interface(s).

The following figure illustrates the safety interface between the chip and the SBC or PMIC.

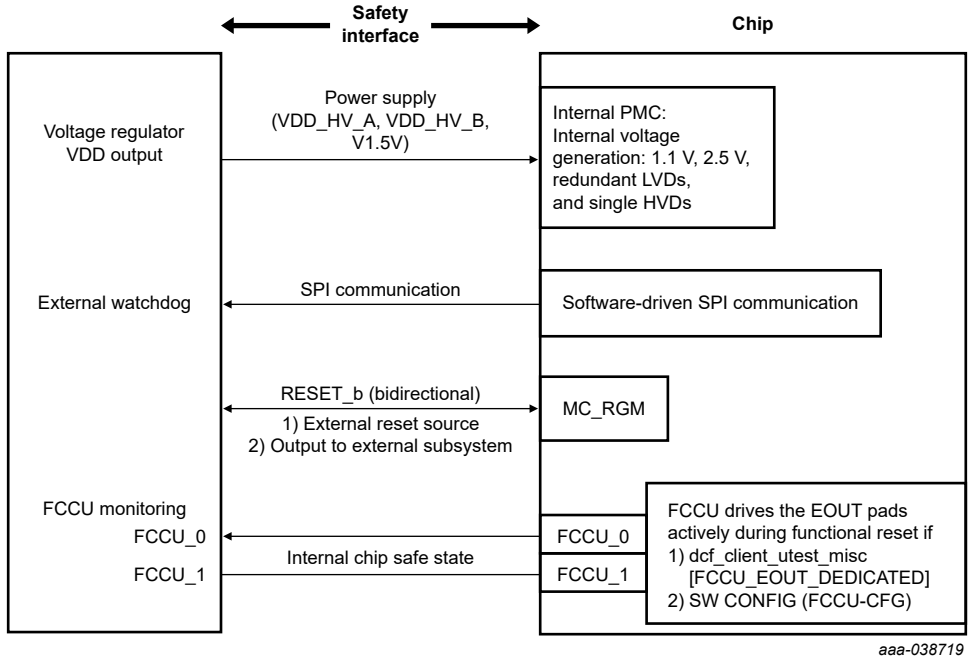

Figure 202. Safety interface between the chip and the SBC or PMIC

In the safety context, the chip interfaces can be classified into the groups shown in the table.

Table 268. Chip interface groups

Interface	Description
Power supply	This interface is between the SBC and the chip. It ensures that the supply to the chip is in the correct range. In case of any low-voltage event, the chip has POR, LVR, and LVD circuits in place and in case of any HVD event, the chip raises an interrupt. The SBC must ensure that the voltage regulator outputs never exceed the allowed range (more specifically for HVD range).
Communication	Responsible for communication between the SBC and the chip. Though the chip supports multiple communication protocols (UART, LIN, SPI, I2C, FlexCAN, and so on), SPI is the preferred communication with SBC. This is relevant to initialize an external watchdog when the chip is inoperative for a considerably long time (this is indicated by the pin states of the communication interface).
Reset	The chip consists of a reset bidirectional pin interfaced with SBC. The SBC can initiate a chip reset via this pin as a safety reaction in case of: • Extreme critical faults • An inoperative chip • Stuck cases based on the criticality and the application requirements The SBC also samples the reset pin state to identify the chip condition (whether in running state or in reset).
FCCU	The chip indicates the chip faults to the SBC via FCCU EOUT pins through this interface.

The interfaces in Table 268 ensure the chip's operational safety and integrity.

49.2 Safety architecture elements

The chip safety architecture consists of following elements that operate in an interconnected way to meet the ASIL requirements:

- Cortex-M7 core complex (including the cache controllers) operating in delayed lockstep (ASIL D only)
- eDMA controller
- Internal windowed watchdogs with independent clock sources
- Power supply monitoring with redundant low-voltage detectors, single high-voltage detectors, and internal ADC connection to check the internal voltages during application
- Robust clock monitoring, including PLL loss of lock detection
- Embedded flash memory with ECC SECDED and address encoding (parallel address path) check
- System RAM with ECC SECDED and error detection
- Cortex-M7 cache memories with ECC SECDED
- Peripherals memories (EMAC, FlexCAN) with ECC SECDED

- End-to-End EDC (E2E EDC), with address encoding and monitoring of the control signals done by a dedicated module (EDC interface gaskets and XBIC). This ensures the safety of storage operations and of the data path to the internal storage (RAM, flash memory, core cache) and peripherals across the crossbar switch. See the XBIC chapter for details.
- Hardware CRC module that supports end-to-end data check integrity for any data transfer in the system (SRAM to peripherals via DMA transfer, external interfaces to SRAM/peripherals, and so on)
- Cortex-M7 MPUs
- XRDC for memory and peripheral protection
- AIPS_Lite peripheral protection with trusted master-slave connection
- Register protection mechanism for safety-critical registers
- On-chip temperature sensor for temperature monitoring
- Hardware self-test that can be triggered by software:
  - LBIST to detect latent faults in functional logic as well as in safety integrity mechanisms

NOTE

LBIST is not supported in S32K312, S32K311, and S32K310.

  - MBIST to ensure integrity of the memories in the chip (SRAM, ITCM, DTCM, peripheral memories, and so on)
- ADC self-test
- FCCU for error collection and reaction, including reporting error status to system; FCCU supports these programmable reaction types:
  - Interrupt
  - Functional reset
- Error pads indicate the chip's internal state to the external chip interface or SBC.
- EIM to inject errors into the memories and interface gaskets to verify the error-detection features of the memory controllers and the interface gaskets
- ERM to collect diagnostic information from memory controllers in case of an error event

These hardware elements can be supported by software safety measures, for example a structural core self-test or the check-the-checker software library.

49.3 I/O peripherals

The arrangement of I/O peripherals across peripheral bridges allows redundant use of peripherals while limiting possible causes of CCF. Redundant use includes using equivalent peripherals in a replicated way as well as using functionally different peripherals in, for example, feedback measurement loops. Comparison of redundant operation is the responsibility of the application software, not the safety hardware mechanism.

The peripherals are distributed evenly across the peripheral bridges (AIPS*n*), except for singular modules like EMAC, QuadSPI, and so on.

NOTE

EMAC and QuadSPI are not present in S32K312 and S32K311.

49.4 Self-test

The chip supports a self-test operation. Your safety software must initiate the self-test operation by configuring STCU2; the chip does not initiate it. STCU2 then controls the self-test operation. Self-test supports both MBIST and LBIST. After the self-test operation completes, the chip enters a reset sequence. Self-test results are stored in STCU2 and your safety software can read the results after the reset sequence.

Figure 203 depicts the processing steps related to the self-test operation, and its linkage to the chip reset and an application start. You decide whether to run a self-test or to skip it before starting an application. You must also specify the self-test configuration before relinquishing control to STCU2 for performing the self-test operation. This processing finishes by reentering the chip reset sequence, depending on whether the chip encountered an unrecoverable fault during the self-test operation. When an unrecoverable fault is encountered during the self-test operation, the chip enters a reset sequence by performing a destructive reset. When no such fault is encountered, the self-test operation completes by entering the chip sequence with a functional reset sequence. You can prevent reset cycling by limiting the amount of resets permitted; the chip shuts down when this limit has been reached. See the "Functional reset escalation" and "Destructive reset escalation" sections in the MC_RGM chapter.

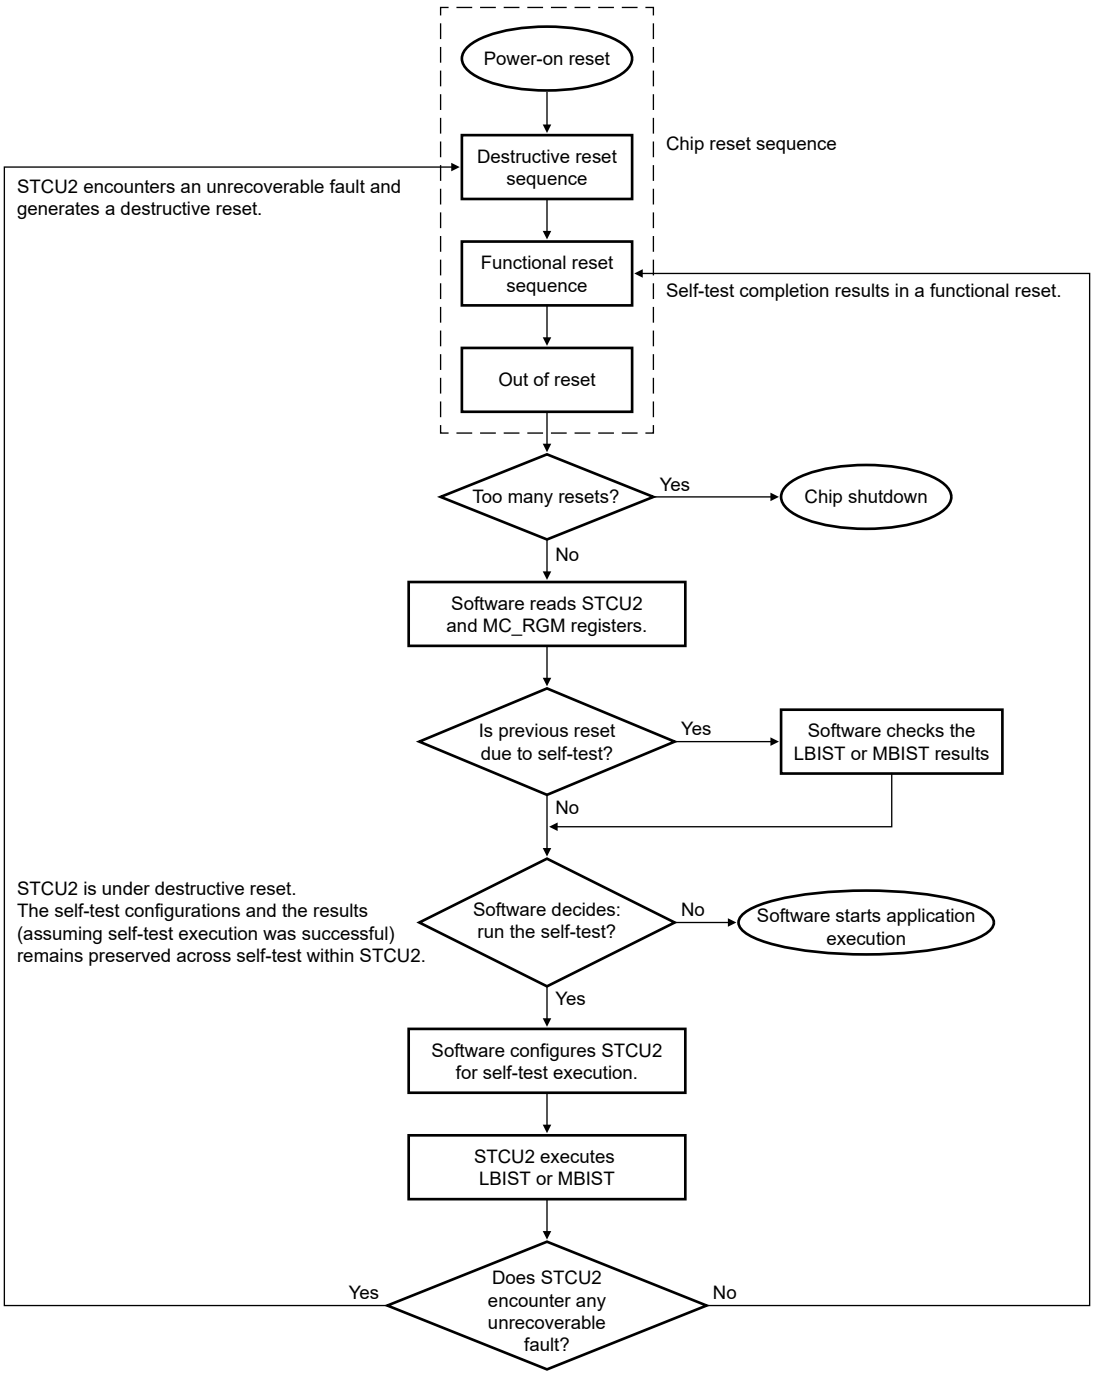

Figure 203. LBIST/MBIST execution

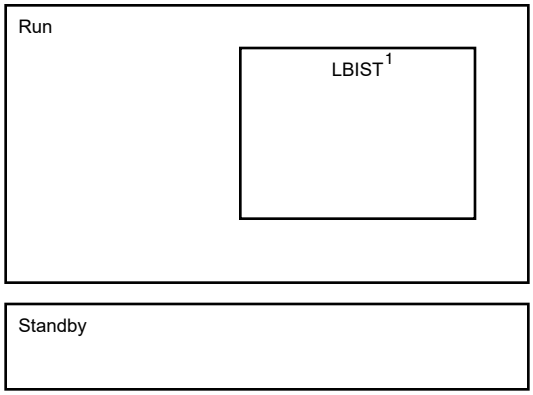
Figure 204 visualizes the top-level partitioning of the chip. The chip consists of two partitions, Run and Standby.

- Run: This partition consists of logic which is present in switchable domain and is shut off (has no supply) while the chip operates in low-power (Standby) mode.
- Standby: This partition consists of always-on logic which is functional even while the chip operates In low-power (Standby) mode.

The Run partition also contains the control logic that is essential for the chip self-test operation, as well as blocks that undergo self-test. The chip consists of a single LBIST partition, which is a subpartition within the Run partition. The LBIST subpartition contains the logic over which self-test is executed. The logic outside the LBIST subpartition and within the Run partition consists of the LBIST control logic as well as logic which does not undergo LBIST.

The Standby partition cannot participate in the LBIST of the Run partition because it is a different partition of the chip. Any module within the Standby partition is therefore excluded from the LBIST. The components within the Standby partition are listed within the section "Chip power domain partitioning" in the "Power Management" chapter.



1. LBIST is not supported on S32K312 and S32K311

Figure 204. S32K3xx chip top-level partition view

See "STCU2 LBIST/MBIST mapping" in the STCU chip-specific section for modules participating in the LBIST operation.

NOTE

REG_PROT of an IP undergoes (or does not undergo) LBIST in conjunction with the protected module that undergoes (or does not undergo) LBIST.

The modules that are vital to the self-test operation are excluded from LBIST regions to allow LBIST to execute successfully.

You must run self-test with PLLDIG configured as the system clock. The LBIST clock controller controls the clock during serial shift, but returns clock control to the functional nodes during the self-test.

49.5 Glossary

ASIL	Automotive safety integrity level. This is a risk classification scheme as defined by ISO 26262 for automotive standard.
CCF	Common cause failure
DTCM	Data tightly coupled memory
ECC	Error correction code
EDC	Error detection code
ITCM	Instruction tightly coupled memory
LBIST	Logic built-in self-test
MBIST	Memory built-in self-test

PLL	Phase-locked loop oscillator
PMIC	Power management integrated chip
SECDED	Single error correction, Double error detection
SBC	System basis chip

Chapter 50
Error Injection Module (EIM)

50.1 Chip-specific EIM information

50.1.1 EIM instances

This chip supports up to four instances of EIM:

- EIM_0
- EIM_1
- EIM_2
- EIM_3

Table 269. EIM instances

Instances	S32K388/S32K389	S32K358/S32K348/S32K338/ S32K328	S32K322/S32K324/S32K344/S32K342/S32K341/ S32K314/S32K312/S32K311/S32K310
EIM_0	Yes	Yes	Yes
EIM_1	Yes	Yes	No
EIM_2	Yes	Yes	No
EIM_3	Yes	No	No

50.1.2 EIM0 base address

Table 270. EIM0 base address

EIM0 base address	Variants
0x4025_8000	S32K322/S32K324/S32K344/S32K342/S32K341/S32K314/S32K312/S32K311/ S32K310
0x4050_C000	S32K388/S32K389/S32K358/S32K348/S32K338/S32K328

50.1.3 EIM channel mapping

EIM integrates with the memory controller and memory array to enable error injection in a controlled way. Each memory controller has its own EIM channel.

Cortex-M7_1, EMAC, AIPS2 gasket, Cortex-M7 lockstep, and QuadSPI gasket are not available in the S32K312 and S32K311 product variants of the S32K3 family.

Table 271. EIM channel mapping - S32K3x1, S32K3x2, S32K344/S32K324/S32K314

Channel #	Target	Data bits [1]	Check bits[1]	# of data bits	# of check bits
0	SRAM0	Word1[31:0] – SRAM0 read data[63:32]	Word0[31:24] – SRAM0 read data ECC[7:0]	64	8
		Word2[31:0] – SRAM0 read data[31:0]

1. You must write to EICHDi_WORDj registers to inject errors in the desired data and check bits. For details, see tables "Error injection channel descriptor: DATA_MASK details" and "DATA_MASK bit: Channel-word mapping" in this chapter.
2. SRAM1 is not available for the S32K342/S32K322/S32K341, S32K312, and S32K311 variants.
3. Applicable for S32K342, S32K341, and S32K322 only.

The two enables, GEIEN and EICHEN*n*, enable the error injection functionality. The former enables it globally and the latter does it for a particular channel. This double-layer enable provides protection against accidental enabling and reconfiguration of the error injection function for each channel.

EIM provides support for inducing single-bit and multi-bit inversions on read data when accessing peripheral RAMs through its data mask registers.

NOTE

For enabling error injection on EDC gaskets (corresponding to channel 28, channel 29, and channel 30), you must also enable the fields corresponding to the required EDC gasket in the MSCM_ENEDC register before enabling the EIM channel.

EIM_EICHD1_CH01, EIM_EICHD1_CH08, EIM_EICHD1_CH09, EIM_EICHD1_CH10, EIM_EICHD1_CH11, EIM_EICHD1_CH12, EIM_EICHD1_CH16, EIM_EICHD1_CH17, EIM_EICHD1_CH18, EIM_EICHD1_CH19, EIM_EICHD1_CH21, EIM_EICHD1_CH22, EIM_EICHD1_CH24, EIM_EICHD1_CH26, EIM_EICHD1_CH27 are not present in S32K312 and S32K311, hence the registers corresponding to these channels are also not present in S32K312 and S32K311.

Table 272. EIM_0 channel mapping - S32K358/S32K348/S32K338/S32K328

Channel Number	Target	Data bits	Check bits	Num of data bits	Num of check bits

Table 274. EIM_2 channel mapping - S32K358/S32K348/S32K338/S32K328 (continued)

Channel Number	Target	Data bits	Check bits	Num of data bits	Num of check bits
		Word1[13:12] – Inject error on AIPS2 write data checker Word1[15:14] – Inject error on 32-bit TCM Cortex-M7_0 path write data checker Word1[17:16] – Inject error on 32-bit TCM Cortex-M7_1 path write data checker			
31	EDC gaskets rdata	Word1[1:0] – Inject error on Cortex-M7_0 AHBM read data checker Word1[3:2] – Inject error on Cortex-M7_0 AHBP read data checker Word1[5:4] – Inject error on DMA read data checker Word1[7:6] – Inject error on STAM read data checker Word1[9:8] – Inject error on HSE read data checker Word1[11:10] – Inject error on EMAC read data checker Word1[13:12] – Inject error on Cortex-M7_1 AHBM read data checker Word1[15:14] – Inject error on Cortex-M7_1 AHBP read data checker Word1[17:16] – Inject error on 32-bit TCM bus path read data checker	-	18	0

1. This tcm gasket is not present for S32K358, S32K338, S32K388, and S32K389. Hence, the channel 6 for EIM_2 is unused.

Table 275. EIM_0 channel mapping - S32K388/S32K389

50.1.4 Behavior of EIM error injection on gaskets

The error injection on gaskets don't impact the actual data flow. The gasket read data, write data and the monitor error don't get changed when EIM error injection is done. The gasket compares the actual data with the modified data (with error injection) and flags the gasket alarm. In case of single-bit error also, the alarm is flagged.

NOTE

The channels which depict such behavior are the gasket channels. See section "EIM channel mapping" in this chapter for details.

50.1.5 Constraints to use EIM on CM7 cache memories

The Cortex-M7 processor has Error Correcting Code (ECC) functionality for error detection and correction that is included in the data and instruction caches when implemented. If hard, or permanent errors occur on the cache RAM, the clean, invalidate and retry scheme might cause a deadlock, and the access is continuously replayed. To prevent this, error bank registers are provided to mask the faulty locations as unusable and invalid. To ensure such a deadlock scenario does not occur while testing the cache memory using EIM module, you must take care of the following points:

- Inject one single-bit error on a cache line at a time.
- Ensure that at least one error bank register of the tested cache is free before injecting any faults. This is to make sure that the fault recovery mechanism of the Cortex-M7 core works.

See ‘Cache RAM protection’ section in the Arm Cortex-M7 Processor Technical Reference Manual for more details.

NOTE

- For S32K338, S32K348, S32K328, S32K358, S32K388. and S32K389: Error injection on 0th and 1st bit for Icache and Dcache is invalid since the Icache and Dcache size is 16 KB.
- For remaining S32K3xx variant: Error injection on 0th bit for Icache and Dcache is invalid since the Icache and Dcache size is 8 KB.

50.2 Overview

The Error Injection Module (EIM) is mainly used for diagnostic purposes. It provides a method to test the diagnostics (memory ECC, interconnect parity) by error injection in the field. See the chip-specific EIM information to determine which functional safety features are supported by this method.

EIM enables you to inject artificial errors on error-checking mechanisms of a system, such as ECC for RAM read data and parity bits. For each such mechanism that EIM supports on the chip, EIM can inject single-bit and multi-bit inversions on data in the applicable target bus. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

50.2.1 Features

The EIM includes these features:

- Supports 17 error injection channels. See the chip-specific EIM information for channel assignment details.
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

50.2.2 Block diagram

The following diagram shows an example of EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

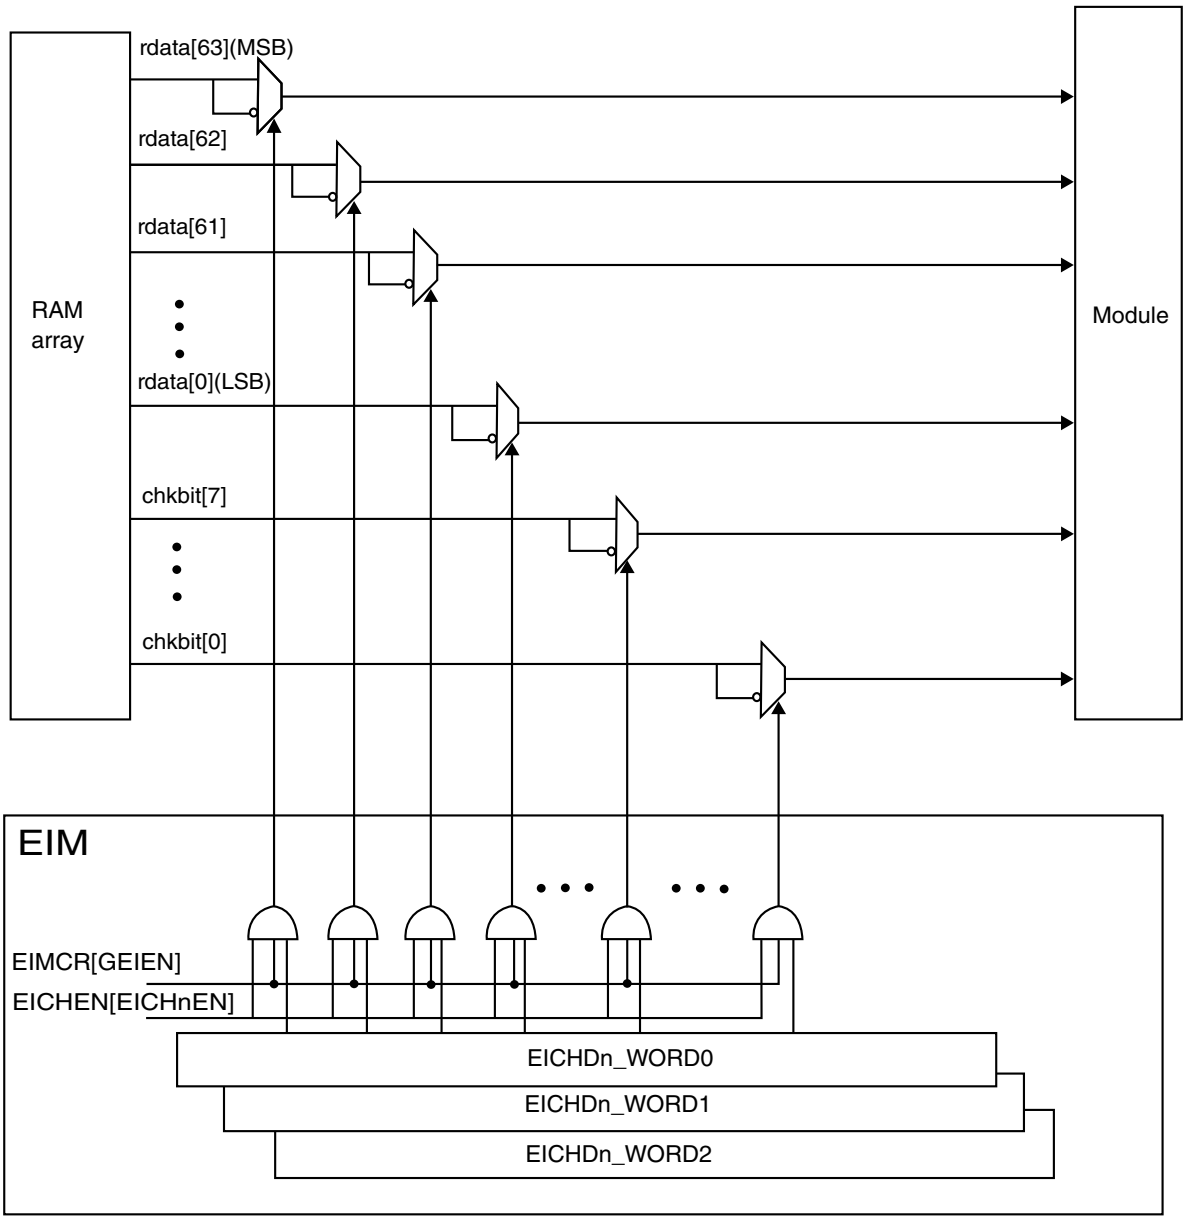

Figure 205. EIM functional block diagram (64-bit read data bus and 8-bit check bit bus)

Several memory elements are implemented within a device, which may not only be the large memory blocks (Flash and SRAM) but also smaller memories like caches, the TCD blocks, and the embedded peripheral memories. Some larger memories may actually be built from multiple memory elements, dependent on their size or function. Each of these memory elements implements its own control logic, the memory controller, that performs the accesses to the actual memory, the memory array. An EIM channel is associated with a memory controller and provides the capability to alter one or multiple signals in the read access path from the corresponding memory array(s). Only memory controllers controlling a safety related memory may be associated with an EIM channel.

50.3 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel:

- Write 1 to the EICHEN[EICH*n*EN] field, where *n* denotes the channel number.

- Write 1 to EIMCR[GEIEN].

NOTE

When the use case for a channel requires writing any EICHD*n*_WORD register, write the EICHD*n*_WORD register before executing the two-stage enablement mechanism. A successful write to any EICHD*n*_WORD register clears the corresponding EICHEN[EICH*n*EN] field.

The EIM supports 17 error injection channels. See the chip-specific EIM information for channel assignment details. Each channel:

- Can be assigned to a single memory array interface by intercepting the assigned memory read data bus and checkbit bus, and injects errors by inverting the value transmitted for selected bits on each bus line.
- Can be assigned to a redundant comparison unit by intercepting the signals being compared, and injecting errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHD*n*_WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 205 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

Error injection scenarios

The EIM supports these cases of error injection:

- To generate a single-bit error, invert only 1 bit of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.
- To generate a multi-bit error, invert only 2 bits of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.

NOTE

An attempt to invert more than 2 bits in one operation might result in undefined behavior.

To enable error injection:

1. Set the EICHD*n*_WORD*m*[CHKBIT_MASK] and EICHD*n*_WORD*m*[B*a*_*b*DATA_MASK] fields for each channel that will be driving an injection.
2. Program the EICHEN register to enable the channels that will be injecting errors.
3. Set the EIMCR[GEIEN] field to globally allow all enabled channels to actively inject errors.

To disable error injection, either disable the EIMCR[GEIEN] field or disable the individual channel enable fields of the EICHEN register.

50.4 Initialization

This module does not require initialization.

50.6 EIM_0 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 280. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in

50.6.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Fields

Field	Function
31 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 0 1b - Error injection is enabled on Error Injection Channel 0
30 EICH1EN	Error Injection Channel 1 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 1 1b - Error injection is enabled on Error Injection Channel 1
29 EICH2EN	Error Injection Channel 2 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

50.6.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0)

Offset

Register	Offset
EICHD0_WORD0	100h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CHKBIT_MASK														0	
W

R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-18 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[13:0] (14 bits wide), CHKBIT_MASK[13] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
17-0 —	Reserved

50.6.5 Error Injection Channel Descriptor 0, Word1 (EICHD0_WORD1)

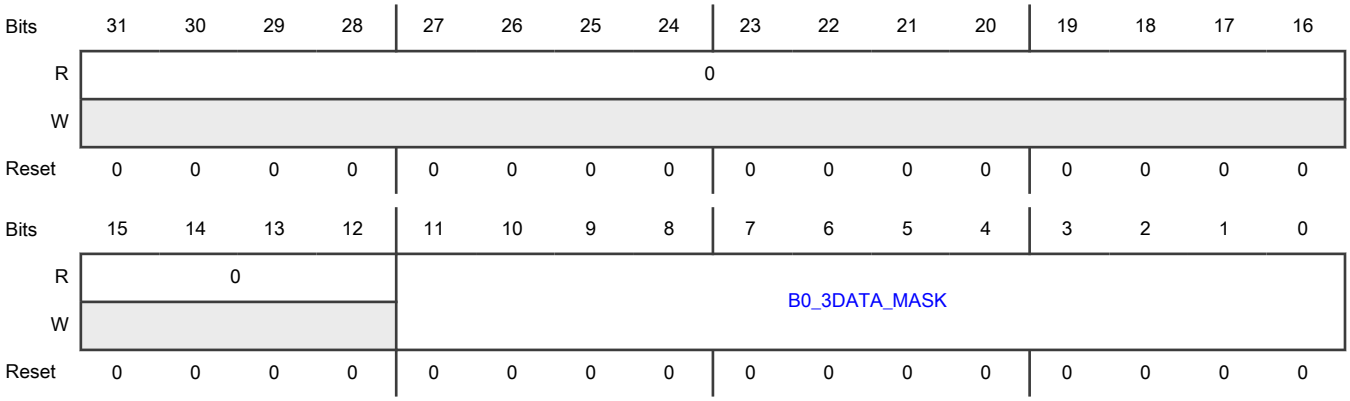
Offset

Register	Offset
EICHD0_WORD1	104h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

50.6.6 Error Injection Channel Descriptor n, Word2 (EICHD0_WORD2 - EICHD13_WORD2)

Offset

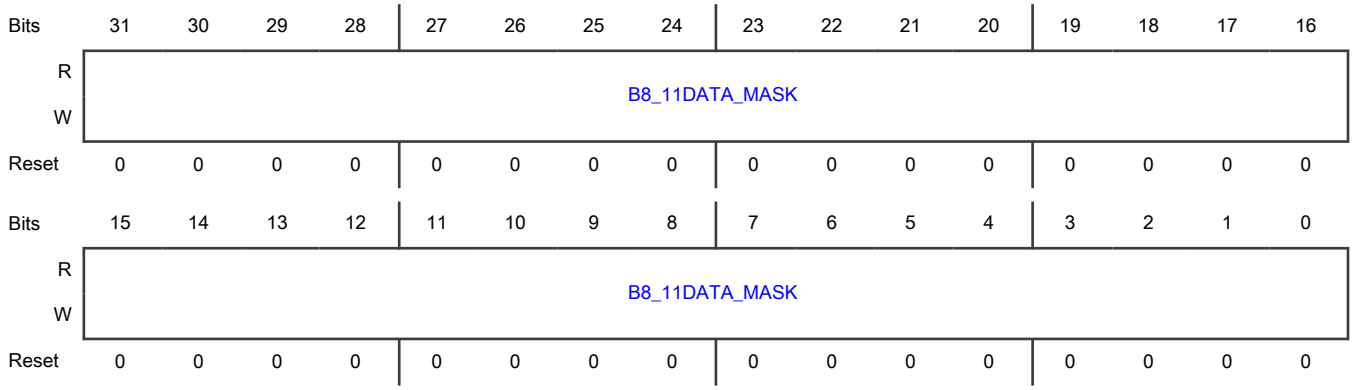
EICHD6_WORD3	28Ch
EICHD7_WORD3	2CCh
EICHD8_WORD3	30Ch
EICHD9_WORD3	34Ch

Function

The fourth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B8_11DATA_MASK correspond to bytes 8–11 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-0 B8_11DATA_MASK	Data Mask Bytes 8-11 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B8_11DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 8-11 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 8-11 on the read data bus is inverted.

50.6.10 Error Injection Channel Descriptor n, Word4 (EICHD1_WORD4 - EICHD9_WORD4)

Fields

Field	Function
31-0 B12_15DATA_MASK	Data Mask Bytes 12-15 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B12_15DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 12-15 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 12-15 on the read data bus is inverted.

50.6.11 Error Injection Channel Descriptor n, Word0 (EICHD2_WORD0 - EICHD4_WORD0)

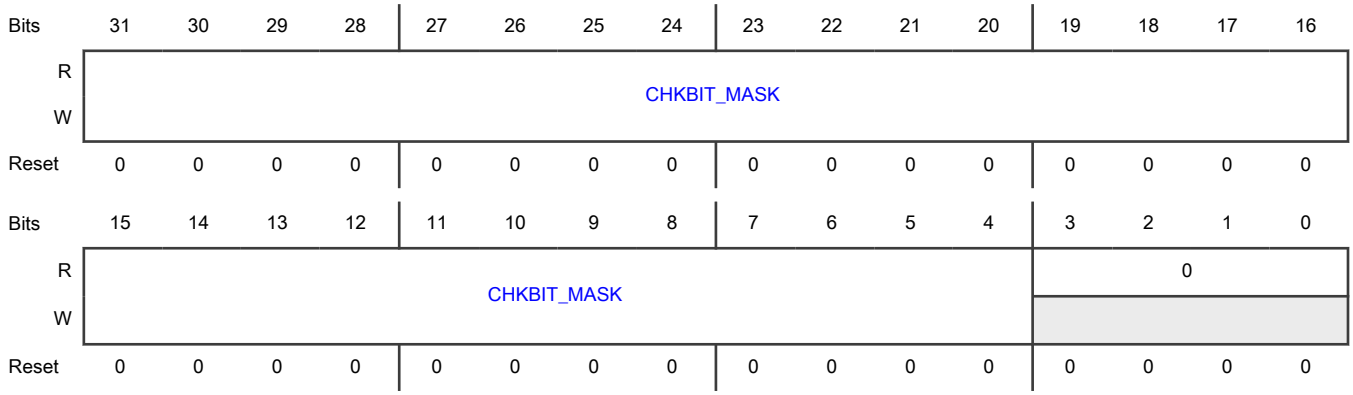
Offset

Register	Offset
EICHD2_WORD0	180h
EICHD3_WORD0	1C0h
EICHD4_WORD0	200h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-4 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[27:0] (28 bits wide), CHKBIT_MASK[27] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
3-0 —	Reserved

50.6.12 Error Injection Channel Descriptor 2, Word1 (EICHD2_WORD1)

Offset

Register	Offset
EICHD2_WORD1	184h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

50.7 EIM_1 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 282. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in

50.7.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Fields

Field	Function
31 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 0 1b - Error injection is enabled on Error Injection Channel 0
30 EICH1EN	Error Injection Channel 1 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 1 1b - Error injection is enabled on Error Injection Channel 1
29 EICH2EN	Error Injection Channel 2 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

50.7.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0)

Offset

Register	Offset
EICHD0_WORD0	100h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-18 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[13:0] (14 bits wide), CHKBIT_MASK[13] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
17-0 —	Reserved

50.7.5 Error Injection Channel Descriptor 0, Word1 (EICHD0_WORD1)

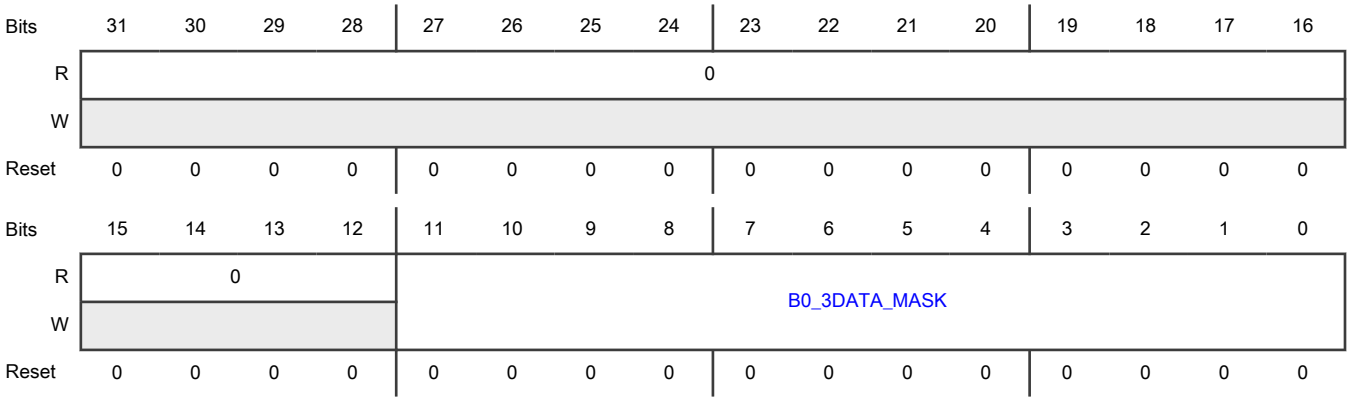
Offset

Register	Offset
EICHD0_WORD1	104h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

Function

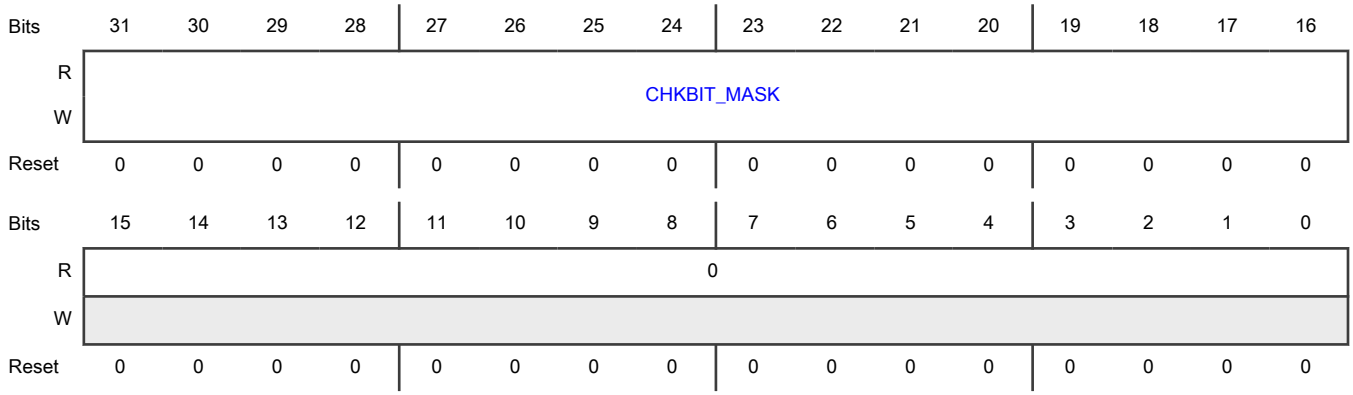
The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-4 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[27:0] (28 bits wide), CHKBIT_MASK[27] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
3-0 —	Reserved

50.7.12 Error Injection Channel Descriptor 2, Word1 (EICHD2_WORD1)

Offset

Register	Offset
EICHD2_WORD1	184h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

50.8 EIM_2 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 284. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in		
		WORD1	WORD2	WORD3
0	64	63-32	31-0	—

50.8.2 Error Injection Module Configuration Register (EIMCR)

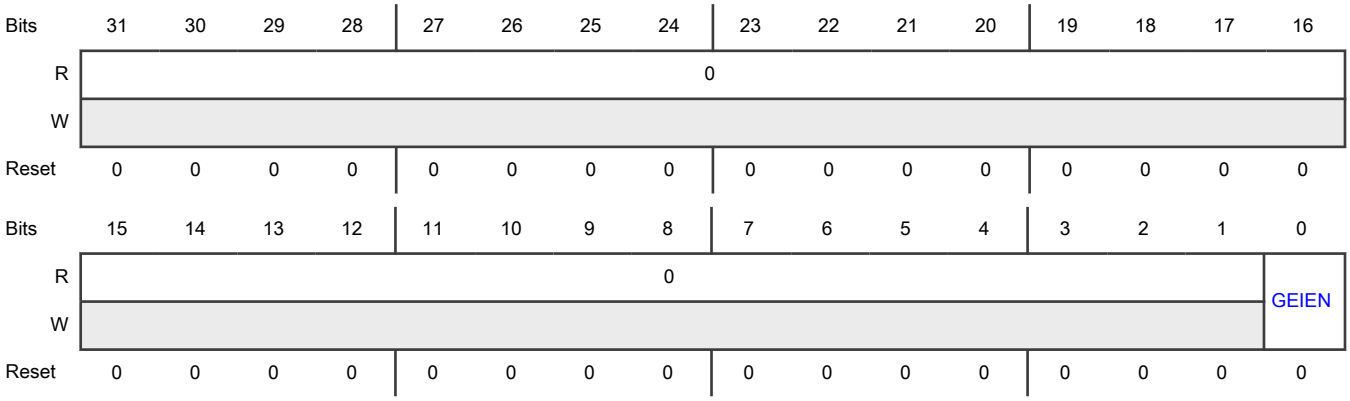
Offset

Register	Offset
EIMCR	0h

Function

The EIM Configuration Register is used to globally enable/disable the error injection function.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 GEIEN	Global Error Injection Enable This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset. 0b - Disabled 1b - Enabled

50.8.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Fields

Field	Function
31 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 0 1b - Error injection is enabled on Error Injection Channel 0
30 EICH1EN	Error Injection Channel 1 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 1 1b - Error injection is enabled on Error Injection Channel 1
29 EICH2EN	Error Injection Channel 2 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

50.8.4 Error Injection Channel Descriptor n, Word0 (EICHD0_WORD0 - EICHD3_WORD0)

Offset

Register	Offset
EICHD0_WORD0	100h
EICHD1_WORD0	140h
EICHD2_WORD0	180h
EICHD3_WORD0	1C0h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CHKBIT_MASK								0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[7:0] (8 bits wide), CHKBIT_MASK[7] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - The corresponding bit of the checkbit bus is inverted.
23-0 —	Reserved

50.8.5 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD3_WORD1)

Offset

Register	Offset
EICHD0_WORD1	104h
EICHD1_WORD1	144h
EICHD2_WORD1	184h
EICHD3_WORD1	1C4h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Function

The third word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B4_7DATA_MASK correspond to bytes 4–7 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

50.9 EIM_3 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 128-bit (16-byte) structure, composed of four 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1-3 (EICHD*n*_WORD1-3), if present, define the data mask. Word2 and Word3 are present only when required by the total width of the channel's data mask. See Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following table shows the total width of DATA_MASK and the distribution of its bits across the WORD registers.

Table 286. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in		
		WORD1	WORD2	WORD3
0	60	59-32	31-0	—
1	60	59-32	31-0	—

	After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 6 1b - Error injection is enabled on Error Injection Channel 6
24 EICH7EN	Error Injection Channel 7 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 7 1b - Error injection is enabled on Error Injection Channel 7
23 EICH8EN	Error Injection Channel 8 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 8 1b - Error injection is enabled on Error Injection Channel 8
22 EICH9EN	Error Injection Channel 9 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 9 1b - Error injection is enabled on Error Injection Channel 9

50.9.4 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD1_WORD1)

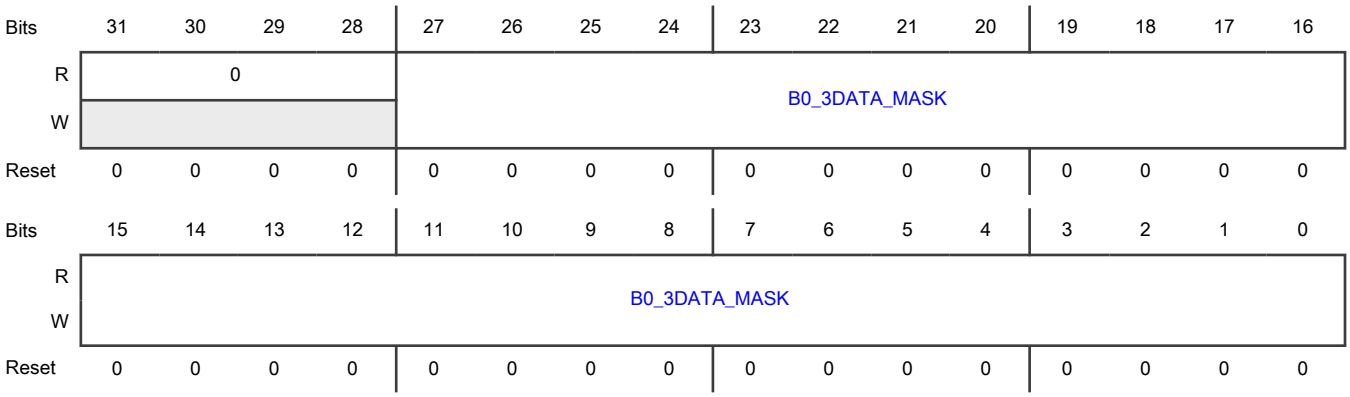
Offset

Register	Offset
EICHD0_WORD1	104h
EICHD1_WORD1	144h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-28 —	Reserved
27-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

50.9.5 Error Injection Channel Descriptor n, Word2 (EICHD0_WORD2 - EICHD6_WORD2)

Offset

Register	Offset
EICHD0_WORD2	108h
EICHD1_WORD2	148h
EICHD2_WORD2	188h

Table continues on the next page...

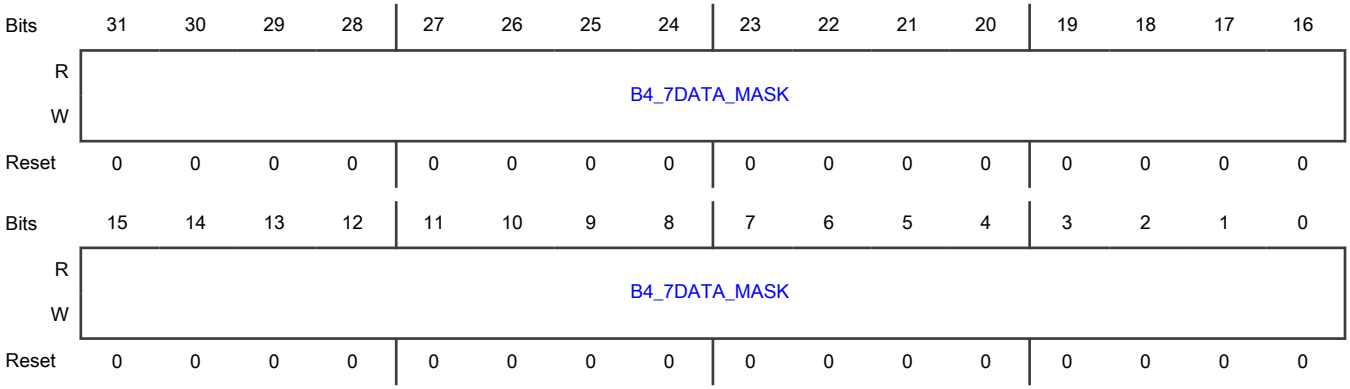
Table continued from the previous page...

Register	Offset
EICHD3_WORD2	1C8h
EICHD4_WORD2	208h
EICHD5_WORD2	248h
EICHD6_WORD2	288h

Function

The third word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B4_7DATA_MASK correspond to bytes 4–7 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-0 B4_7DATA_MASK	Data Mask Bytes 4-7 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B4_7DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 4-7 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 4-7 on the read data bus is inverted.

50.9.6 Error Injection Channel Descriptor n, Word0 (EICHD2_WORD0 - EICHD6_WORD0)

Offset

Register	Offset
EICHD2_WORD0	180h
EICHD3_WORD0	1C0h
EICHD6_WORD0	280h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram

ECC	Error correction code

Chapter 51
Error Reporting Module (ERM)

51.1 Chip-specific ERM information

51.1.1 ERM instances

This chip supports up to two instances of ERM:

- ERM_0
- ERM_1

Table 287. ERM instances

Instances	S32K358/S32K348/ S32K338/S32K328/ S32K388/S32K389	S32K322/S32K324/S32K344/S32K342/S32K341/S32K312/S32K311/ S32K310/S32K314
ERM_0	Yes	Yes
ERM_1	Yes	No

51.1.2 ERM channel mapping

ERM provides information on memory events associated with ECC and parity. It also provides you an option to enable interrupt notification for these events.

Table 288. ERM_0 channel mapping

Channel #	Module	Captured status
00	SRAM0	Single-bit error, multi-bit error, syndrome, absolute error address aligned to double-word (64-bit) boundary
01	SRAM1 [1]	Single-bit error, multi-bit error, syndrome, absolute error address+18000h aligned to double-word (64-bit) boundary[2]
02	Cortex-M7_0 I-cache tag RAM	Single-bit error, multi-bit error[3]
03	Cortex-M7_0 I-cache data RAM	Single-bit error, multi-bit error[3]
04	Cortex-M7_0 D-cache tag RAM	Single-bit error, multi-bit error[3]
05	Cortex-M7_0 D-cache data RAM	Single-bit error, multi-bit error[3]
06	Cortex-M7_1 I-cache tag RAM [4]	Single-bit error, multi-bit error[3]
07	Cortex-M7_1 I-cache data RAM	Single-bit error, multi-bit error[3]
08	Cortex-M7_1 D-cache tag RAM	Single-bit error, multi-bit error[3]
09	Cortex-M7_1 D-cache data RAM	Single-bit error, multi-bit error[3]
10	Cortex-M7_0 ITCM	Single-bit error, multi-bit error, syndrome, offset error address
11	Cortex-M7_0 D0TCM	Single-bit error, multi-bit error, syndrome, offset error address
12	Cortex-M7_0 D1TCM	Single-bit error, multi-bit error, syndrome, offset error address[5]
13	Cortex-M7_1 ITCM	Single-bit error, multi-bit error, syndrome, offset error address

Table continues on the next page...

Table 288. ERM_0 channel mapping (continued)

Channel #	Module	Captured status
14	Cortex-M7_1 D0TCM	Single-bit error, multi-bit error, syndrome, offset error address
15	Cortex-M7_1 D1TCM	Single-bit error, multi-bit error, syndrome, offset error address[5]
16	DMA TCD	Single-bit error, multi-bit error, syndrome, offset error address[6]
17	Flash memory port p0	Single-bit error, multi-bit error, absolute error address
18	Flash memory port p1	Single-bit error, multi-bit error, absolute error address
19	Flash memory port p2 [7]	Single-bit error, multi-bit error, absolute error address

1. SRAM1 is not available for the S32K342, S32K341, S32K322, S32K312, and S32K311 product variants.
2. For variants: S32K314, S32K324, and S32K344 size of SRAM0 is 160 KB, and therefore, to align addresses to the next power of 2, an address space of 256 KB is reserved for error reporting. However, SRAM0 and SRAM1 are in contiguous locations in the memory map. So, you must subtract 18000h (256 KB-160 KB = 96 KB that corresponds to 18000h) from the reported address to get an absolute address. See the "Memory and Memory Interfaces" chapter for SRAM details on different S32K3xx variants.
3. The cache controller does not report error addresses and syndrome.
4. Cortex-M7_1 and its associated RAM and caches are not available in the S32K312 and S32K311 product variants.
5. For address reporting, bit 2 of the address is masked because this bit decides whether the access (read or write) is for D0TCM or D1TCM. For example, if the offset address is 0h or 8h, it is routed to D0TCM, but if the offset address is 4h or Ch, it is routed to D1TCM. The errors that are latched for these offset addresses are as follows:
   - Offset 0h : Address 0h is latched into the ERM channel corresponding to D0TCM.
   - Offset 4h : Address 0h is latched into the ERM channel corresponding to D1TCM.
   - Offset 8h : Address 8h is latched into the ERM channel corresponding to D0TCM.
   - Offset Ch : Address 8h is latched into the ERM channel corresponding to D1TCM.
6. Bits [31:10] and [2:0] are always 0 because they are not connected.

   Bits [9:5] indicate the corresponding TCD out of all the 32 implemented TCDs.

   Bits [4:3] indicate an offset of TCDs with respect to a 64-bit aligned boundary.
   - If [4:3] is 00, it indicates that an error is on offset address 20h.
   - If [4:3] is 01, it indicates that an error is on offset address 28h.
   - If [4:3] is 10, it indicates that an error is on offset address 30h.
   - If [4:3] is 11, it indicates that an error is on offset address 38h.
7. Flash memory port p2 is not applicable for the S32K312 and S32K311 product variants.

Table 289. ERM_0 channel mapping for S32K389

Channel #	Module	Captured status
00	SRAM0	Single-bit error, multi-bit error, syndrome, absolute error address aligned to double-word (64-bit) boundary
01	SRAM1	Single-bit error, multi-bit error, syndrome, absolute error address+18000h aligned to double-word (64-bit) boundary
02	Cortex-M7_0 I-cache tag RAM	Single-bit error, multi-bit error[1]
03	Cortex-M7_0 I-cache data RAM	Single-bit error, multi-bit error[1]
04	Cortex-M7_0 D-cache tag RAM	Single-bit error, multi-bit error[1]
05	Cortex-M7_0 D-cache data RAM	Single-bit error, multi-bit error[1]

Table continues on the next page...

Table 289. ERM_0 channel mapping for S32K389 (continued)

Channel #	Module	Captured status
06	Cortex-M7_1 I-cache tag RAM	Single-bit error, multi-bit error[1]
07	Cortex-M7_1 I-cache data RAM	Single-bit error, multi-bit error[3]
08	Cortex-M7_1 D-cache tag RAM	Single-bit error, multi-bit error[3]
09	Cortex-M7_1 D-cache data RAM	Single-bit error, multi-bit error[3]
10	Cortex-M7_0 ITCM	Single-bit error, multi-bit error, syndrome, offset error address
11	Cortex-M7_0 D0TCM	Single-bit error, multi-bit error, syndrome, offset error address
12	Cortex-M7_0 D1TCM	Single-bit error, multi-bit error, syndrome, offset error address[2]
13	Cortex-M7_1 ITCM	Single-bit error, multi-bit error, syndrome, offset error address
14	Cortex-M7_1 D0TCM	Single-bit error, multi-bit error, syndrome, offset error address
15	Cortex-M7_1 D1TCM	Single-bit error, multi-bit error, syndrome, offset error address[2]
16	DMA TCD	Single-bit error, multi-bit error, syndrome, offset error address[3]
17	Flash memory controller PFC0 port 0	Single-bit error, multi-bit error, absolute error address
18	Flash memory controller PFC0 port 1	Single-bit error, multi-bit error, absolute error address
19	Flash memory controller PFC1 port 0	Single-bit error, multi-bit error, absolute error address
20	Flash memory controller PFC1 port 1	Single-bit error, multi-bit error, absolute error address
21	PRAM3	Single-bit error, multi-bit error, absolute error address

1. The cache controller does not report error addresses and syndrome.
2. For address reporting, bit 2 of the address is masked because this bit decides whether the access (read or write) is for D0TCM or D1TCM. For example, if the offset address is 0h or 8h, it is routed to D0TCM, but if the offset address is 4h or Ch, it is routed to D1TCM. The errors that are latched for these offset addresses are as follows:
   - Offset 0h : Address 0h is latched into the ERM channel corresponding to D0TCM.
   - Offset 4h : Address 0h is latched into the ERM channel corresponding to D1TCM.
   - Offset 8h : Address 8h is latched into the ERM channel corresponding to D0TCM.
   - Offset Ch : Address 8h is latched into the ERM channel corresponding to D1TCM.
3. Bits [31:10] and [2:0] are always 0 because they are not connected.

   Bits [9:5] indicate the corresponding TCD out of all the 32 implemented TCDs.

   Bits [4:3] indicate an offset of TCDs with respect to a 64-bit aligned boundary.
   - If [4:3] is 00, it indicates that an error is on offset address 20h.
   - If [4:3] is 01, it indicates that an error is on offset address 28h.
   - If [4:3] is 10, it indicates that an error is on offset address 30h.
   - If [4:3] is 11, it indicates that an error is on offset address 38h.

21	-	-
22	-	-
23	-	-

1. CM7_3 ports are reserved for all chips except S32K388/S32K389.
2. Not applicable for S32K389.

NOTE

For S32K388/S32K389, channel 1 and channel 16 of ERM_1 are Reserved. Read and write to registers related to these channels will not give any transfer error.

NOTE

For S32K358/S32K348/S32K338/S32K328, you have to enable both the ERM instances even if you are only using one otherwise software might hang during interrupt subroutine.

51.1.3 ECC error address remapping (S32K389)

The software driver for the ERM module converts the reported error addresses (physical) to the system logic addresses, as per the table below:

Table 291. ECC error address remapping (S32K389)

PFC0 (ERM Channel #17, #18)	
Physical Address (reported to ERM)	System Logical Address (to be converted to)
0x004x_xxxx	0x006x_xxxx
0x005x_xxxx	0x007x_xxxx
0x006x_xxxx	0x008x_xxxx
0x007x_xxxx	0x009x_xxxx
0x008x_xxxx	0x00Cx_xxxx
0x009x_xxxx	0x00Dx_xxxx
0x00Ax_xxxx	0x00Ex_xxxx
0x00Bx_xxxx	0x00Fx_xxxx
PFC1 (ERM Channel #19, #20)	
Physical Address (reported to ERM)	System Logical Address (to be converted to)
0x004x_xxxx	0x004x_xxxx
0x005x_xxxx	0x005x_xxxx
0x006x_xxxx	0x00Ax_xxxx
0x007x_xxxx	0x00Bx_xxxx

51.2 Overview

The Error Reporting Module (ERM) provides information and optional interrupt notification on memory error events associated with ECC and parity. The ERM collects error events on memory accesses for memory arrays, such as flash memory, system RAM, or peripheral RAMs. ERM supports various channels for memory sources where each ERM channel is associated with a different memory module. See the chip-specific ERM information for details about supported memory sources and specific memory channel assignments. If memory supports ECC then ERM syndrome and error address information is captured along with error event. ERM does not receive this information in case of cache or memory with parity along with error event.

51.2.1 Features

The ERM includes these features:

- Optional interrupt notification on captured error events
- Capturing of address and syndrome information on single-bit correction and non-correctable ECC events
- Support for error event capturing for memory sources, with individual reporting fields and interrupt configuration per memory channel
- Recording the count value of the number of corrected error events

51.2.2 Block diagram

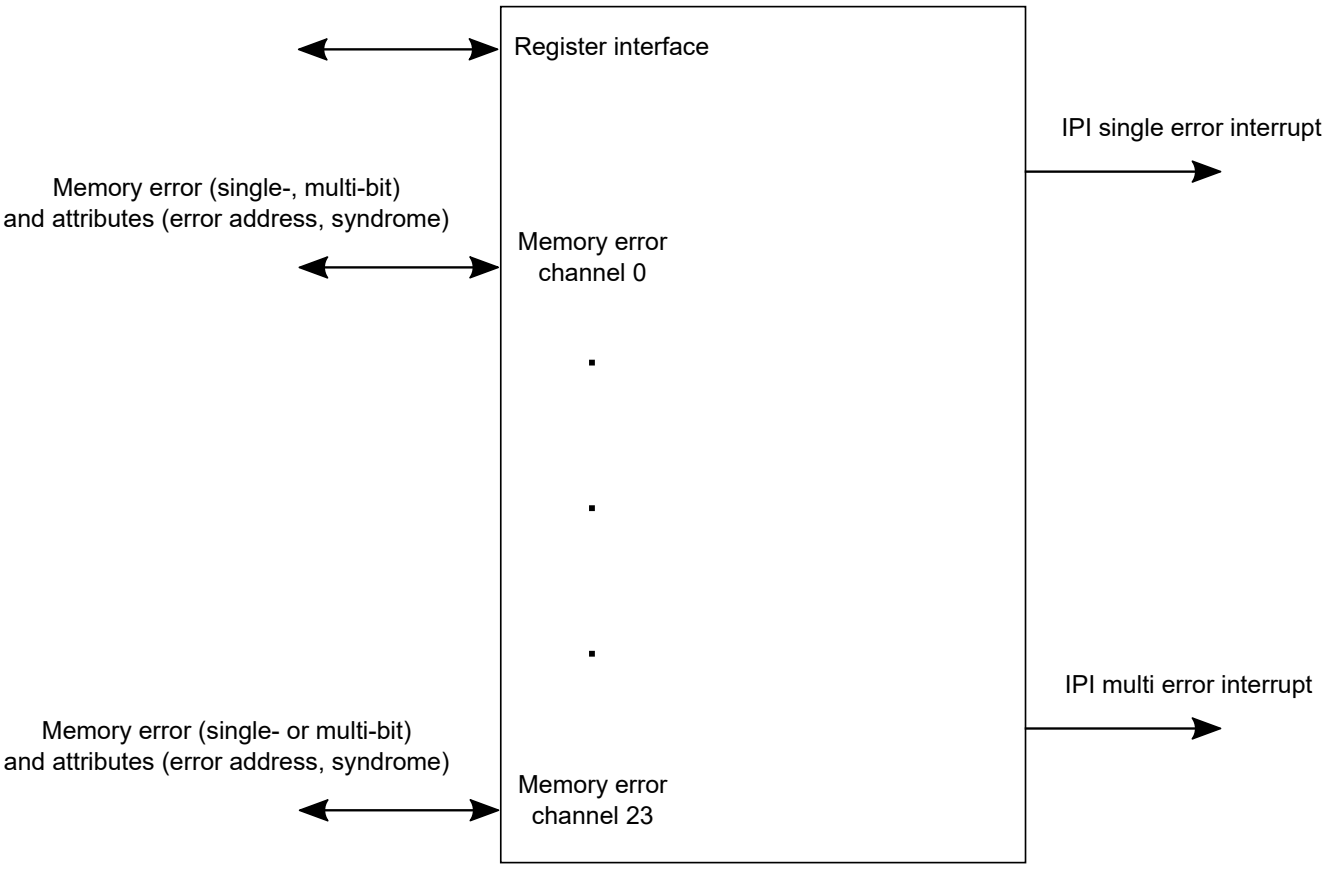

Figure 206. Block diagram

51.3 Functional description

51.3.1 Single-bit correction events

When a single-bit correction event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit SR*x*[SBC*n*] to 1.
- Increments the correctable error count value (until the counter reaches its maximum value): CORR_ERR_CNT*n*[COUNT].
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel). This register identifies the bit position of the corrected data on single-bit data inversion.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[SBC*n*] to change its value to 0.

To reset the correctable error count value, write all zeros to CORR_ERR_CNT*n*[COUNT].

Optional interrupt notification for single-bit correction events

The ERM provides an option to generate an interrupt notification upon the report of a single-bit correction event. To enable single-bit correction interrupts for a channel:

1. To enable interrupt notification for single-bit correction events on Memory *n*, set CR*x*[ESCIE*n*] to 1.
2. Subsequently, when a single-bit correction event on Memory *n* is detected, the ERM:
   - Records the event and address, and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[SBC*n*] to change its value to 0.

51.3.2 Non-correctable error events

When a non-correctable ECC error event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit: SR*x*[NCE*n*] to 1.
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel).
  - In the event of a non-correctable address bit inversion, SYN*n* identifies the pertinent address bit position.
  - In the event of a non-correctable, multi-bit data inversion, the syndrome value does not provide any additional diagnostic information.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[NCE*n*] to change its value to 0.

Optional interrupt notification for non-correctable error events

The ERM provides an option to generate an interrupt notification upon the report of a non-correctable ECC event. To enable non-correctable error interrupts for a channel:

1. To enable interrupt notifications for non-correctable error events on Memory *n*, set CR*x*[ENCIE*n*] to 1.
2. Subsequently, when a non-correctable error event on Memory *n* is detected, the ERM:
   - Records the event and address and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[NCE*n*] to change its value to 0.

NOTE

Parity errors can be mapped to non-correctable errors where error attributes like SYNDROME, ADDRESS are not provided.

51.4 Initialization

For each ERM channel supporting memory with ECC, prepare the corresponding memory array before enabling ERM interrupts about errors for that memory.

1. Initialize the memory to a known value so that the correct corresponding ECC codeword is stored.
2. During the memory's initialization, if the ERM captures information about any ECC error event, clear the corresponding SR*x*[SBC*n*] or SR*x*[NCE*n*] field that stores the record of the event.
3. Program the applicable CR*x*[ESCIE*n*] and CR*x*[ENCIE*n*] fields to enable ERM interrupts as desired.

51.5 ERM_0 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Based on the design implementation, the following XFR error behavior is evident at the IPS interface.

- Within the ERM memory map, an XFR error is evident at reserved addresses from location 20h to FFh.
- No XFR error is evident at reserved addresses in memory spaces allocated to each channel. For example: For channel 0, for read/write accesses to reserved address 10Ch, the XFR error is 0.
- For accesses to locations beyond the addresses allocated for the final channel, the XFR error is 1.

NOTE

- See the chip-specific ERM information at the beginning of this chapter for details on Memory channel mapping.
- To access the channel registers, corresponding memory channel clock must be enabled.

51.5.8 ERM Memory a Error Address Register (EAR0 - EAR21)

Offset

Register	Offset
EAR0	100h
EAR1	110h
EAR10	1A0h
EAR11	1B0h
EAR12	1C0h

Table continues on the next page...

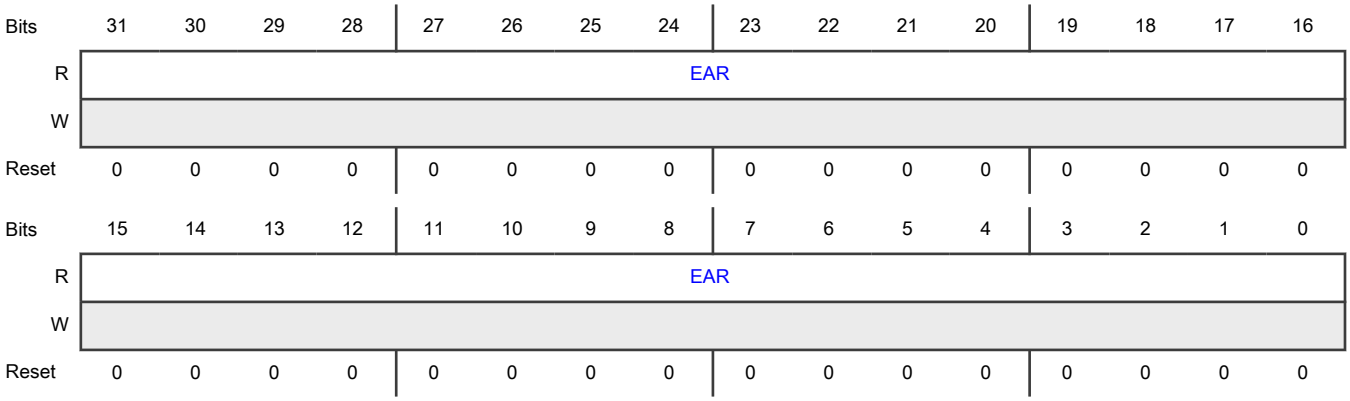
Table continued from the previous page...

Register	Offset
EAR13	1D0h
EAR14	1E0h
EAR15	1F0h
EAR16	200h
EAR17	210h
EAR18	220h
EAR19	230h
EAR20	240h
EAR21	250h

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory*n*, where*n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram



Fields

Field	Function
31-0 EAR	EAR Memory*n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory*n*.

51.5.9 ERM Memory a Syndrome Register (SYN0 - SYN21)

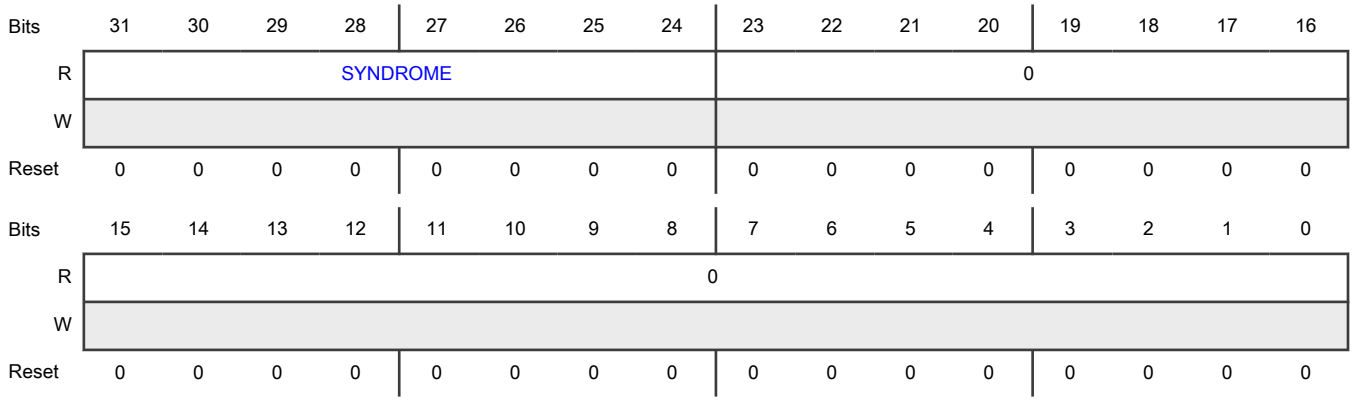
Offset

Register	Offset
SYN0	104h
SYN1	114h
SYN10	1A4h
SYN11	1B4h
SYN12	1C4h
SYN13	1D4h
SYN14	1E4h
SYN15	1F4h
SYN16	204h
SYN21	254h

Function

The ERM Memory *n* Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory*n*, where*n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Diagram



Fields

Field	Function
31-24 SYNDROME	SYNDROME Memory*n* Syndrome — This field contains the ECC syndrome associated with the last recorded ECC event on Memory*n*.

23-0 —	Reserved

51.5.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT21)

Offset

Register	Offset
CORR_ERR_CNT0	108h
CORR_ERR_CNT1	118h
CORR_ERR_CNT2	128h
CORR_ERR_CNT3	138h
CORR_ERR_CNT4	148h
CORR_ERR_CNT5	158h
CORR_ERR_CNT6	168h
CORR_ERR_CNT7	178h
CORR_ERR_CNT8	188h
CORR_ERR_CNT9	198h
CORR_ERR_CNT10	1A8h
CORR_ERR_CNT11	1B8h
CORR_ERR_CNT12	1C8h
CORR_ERR_CNT13	1D8h
CORR_ERR_CNT14	1E8h
CORR_ERR_CNT15	1F8h
CORR_ERR_CNT16	208h
CORR_ERR_CNT17	218h
CORR_ERR_CNT18	228h
CORR_ERR_CNT19	238h
CORR_ERR_CNT20	248h
CORR_ERR_CNT21	258h

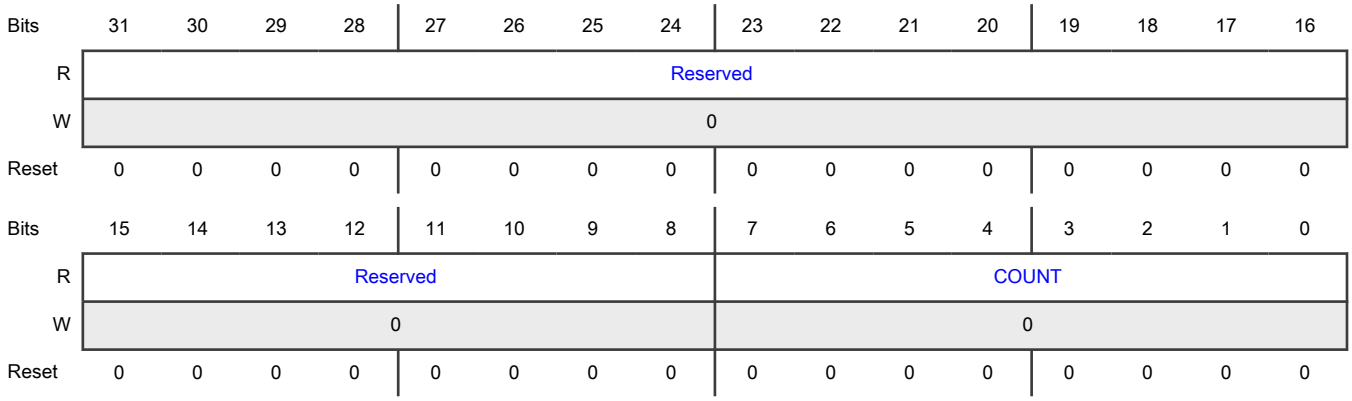
Function

Each 32-bit ERM Memory *n* Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory*n*, where*n* denotes the memory channel.

NOTE

Non-correctable errors are considered a serious fault, so the ERM does not provide any mechanism to count non-correctable errors. Only correctable errors are counted.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT value will stop when it reaches maximum value FFh and will not wrap even if additional errors occur. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing a non-zero value has no effect.

51.6 ERM_1 register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Based on the design implementation, the following XFR error behavior is evident at the IPS interface.

- Within the ERM memory map, an XFR error is evident at reserved addresses from location 20h to FFh.
- No XFR error is evident at reserved addresses in memory spaces allocated to each channel. For example: For channel 0, for read/write accesses to reserved address 10Ch, the XFR error is 0.
- For accesses to locations beyond the addresses allocated for the final channel, the XFR error is 1.

NOTE

- See the chip-specific ERM information at the beginning of this chapter for details on Memory channel mapping.
- To access the channel registers, corresponding memory channel clock must be enabled.

51.6.8 ERM Memory a Error Address Register (EAR0 - EAR19)

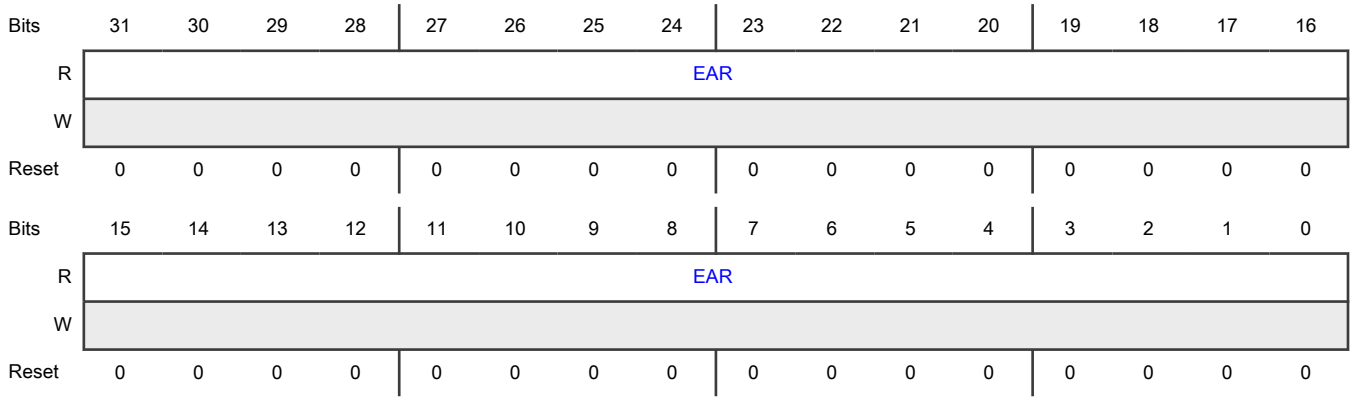
Offset

Register	Offset
EAR0	100h
EAR10	1A0h
EAR11	1B0h
EAR12	1C0h
EAR13	1D0h
EAR14	1E0h
EAR15	1F0h
EAR18	220h
EAR19	230h

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory*n*, where*n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram



Fields

Field	Function
31-0 EAR	EAR Memory*n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory*n*.

51.6.9 ERM Memory a Syndrome Register (SYN0 - SYN19)

Offset

Register	Offset
SYN0	104h
SYN10	1A4h
SYN11	1B4h
SYN12	1C4h
SYN13	1D4h
SYN14	1E4h
SYN15	1F4h
SYN18	224h
SYN19	234h

Function

The ERM Memory *n* Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory*n*, where*n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

51.6.10 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT19)

Offset

Register	Offset
CORR_ERR_CNT0	108h
CORR_ERR_CNT2	128h
CORR_ERR_CNT3	138h
CORR_ERR_CNT4	148h
CORR_ERR_CNT5	158h
CORR_ERR_CNT6	168h
CORR_ERR_CNT7	178h
CORR_ERR_CNT8	188h
CORR_ERR_CNT9	198h
CORR_ERR_CNT10	1A8h
CORR_ERR_CNT11	1B8h
CORR_ERR_CNT12	1C8h
CORR_ERR_CNT13	1D8h
CORR_ERR_CNT14	1E8h
CORR_ERR_CNT15	1F8h
CORR_ERR_CNT18	228h
CORR_ERR_CNT19	238h

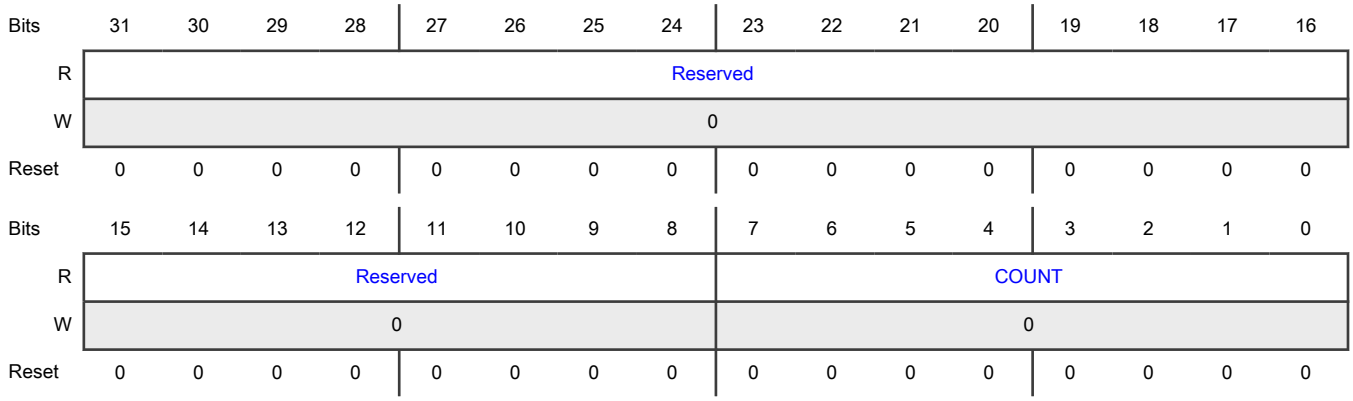
Function

Each 32-bit ERM Memory *n* Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory*n*, where*n* denotes the memory channel.

NOTE

Non-correctable errors are considered a serious fault, so the ERM does not provide any mechanism to count non-correctable errors. Only correctable errors are counted.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT value will stop when it reaches maximum value FFh and will not wrap even if additional errors occur. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing a non-zero value has no effect.

51.7 Glossary

ECC Error correction code

Chapter 52
Fault Collection and Control Unit (FCCU)

52.1 Chip-specific FCCU information

52.1.1 FCCU NCF slots

Table 292. FCCU NCF slots

Slot number	Source module (error type)
NCF[0]	• Cortex-M7 LS and core lockup
NCF[1]	Interconnect: • All EDC bus gaskets • XBIC monitors and platform gaskets • Flash Address Remapping[1]
NCF[2]	ECC errors: • PRAMC • TCMs • Caches • eDMA • EDC after ECC • QuadSPI[2] • AES_ACCEL (include DMA TCD) errors [3]
NCF[3]	All flash memory errors: • FMU • PFLASH • DCM flash memory
NCF[4]	Voltage-related errors: • PMC 1.1 V and 2.5 V GNG • PMC 1.1 V and 2.5 V GNG2[2] • Pad overvoltage
NCF[5]	Debug and test monitoring, STCU faults [4]
NCF[6]	INTM
NCF[7]	Software notification

1. For S32K389 only.
2. For S32K358/S32K348/S32K338/S32K328 only.
3. For S32K388/S32K389 only.
4. The fault would be raised if DBGPWRUPREQ toggles while any core is in halted state. If this operation is expected, the application can ignore/disable such an NCF event.

52.1.2 Chip-boundary FCCU signals

Table 293. Chip-boundary FCCU signals

FCCU signal	Chip signal
EOUT0	FCCU_ERR0
EOUT1	FCCU_ERR1

52.1.3 FCCU clocking

Table 294. FCCU clocking

FCCU clock signal	Chip clock signal
CLKSAFE	FIRC_CLK
CLKPRIM	AIPS_PLAT_CLK

52.1.4 FOSU timer interval

The FOSU_COUNT value determines the FOSU timer interval. On this chip, FOSU_COUNT is 69780h.

52.1.5 Supported internal chip reactions

The short functional reset discussed in this chapter is equivalent to the chip functional reset. See the interrupt map file attached to this document for interrupts from FCCU to NVIC.

NOTE

After STCU2 completes the self-testing procedure, the chip reboots and FCCU resets.

52.1.6 Recommended reaction programming for faults

You can upgrade or downgrade the reaction of the faults according to the recommended reaction discussed in the fault map file attached to this document.

In case you upgrade a reaction, no issues are expected in the behavior. If you downgrade the reaction, the functionality is not guaranteed.

This is the recommendation for faults caused by lockstep errors:

1. The recommended reaction for the lockstep error fault is a functional reset.
2. Program the core to perform the following steps after rebooting:
    a. Initialize TCM (because TCMs can become corrupted)
    b. Invalidate the cache (because caches can become corrupted)
3. Write 1 to the corresponding bit in FCCU.NCF_S0 register to clear the non-critical fault status.
4. If the FCCU fault gets cleared, you have nothing else to do for fault handling (this means, the FCCU lockstep error is recovered).
5. If the error persists, it indicates that the internal registers of the two cores have different values. To bring them to the same value, you could perform any of these steps:
    a. Initialize destructive reset through software by using MC_ME.MODE_CONF[DEST_RST] to recover from lockstep. This initializes the FCCU with no pending faults.
    b. Reconfigure the Cortex-M7 debug configurations (which would have been lost in previous step due to destructive reset in the system).

52.1.7 FCCU NCF handling architecture

This chip supports eight NCFs. Therefore, multiple faults of similar nature are ORed together and then connected as a single NCF to FCCU. To control individual fault, there are enable/disable controls provided within DCM in registers DCMRWD*n*.

Similarly, the FCCU.NCF_S0 captures the status of fault within FCCU. This fault might have resulted due to any fault mapped on the corresponding FCCU NCF channel. The DCM status registers DCMROD*n* capture the status of individual faults which are mapped onto FCCU NCFs. Figure 207 shows this arrangement.

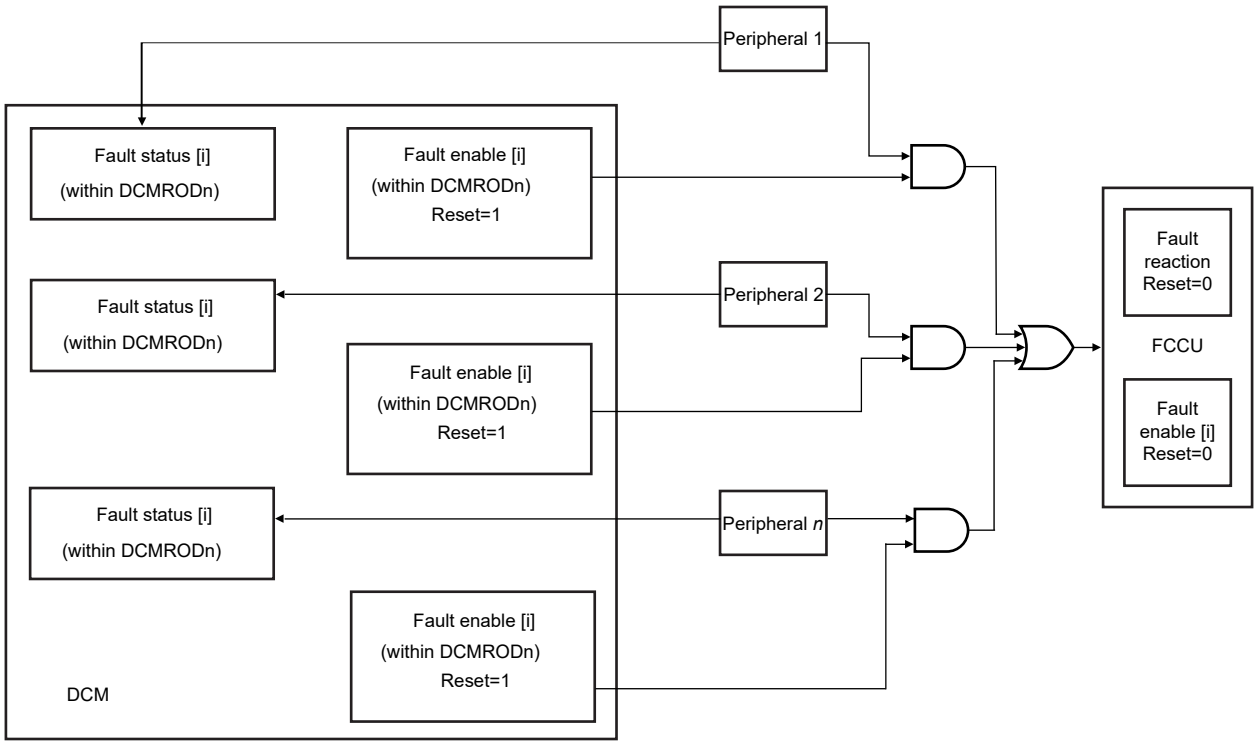


Figure 207. FCCU NCF handling architecture

52.2 Overview

The FCCU provides a hardware interface to collect faults and to place the device into a safe state when a failure is detected in the device. No CPU intervention is requested for collection and control operations. FCCU offers a systematic approach to fault collection and control.

52.2.1 Block diagram

The following figure represents a top-level diagram of the FCCU module.

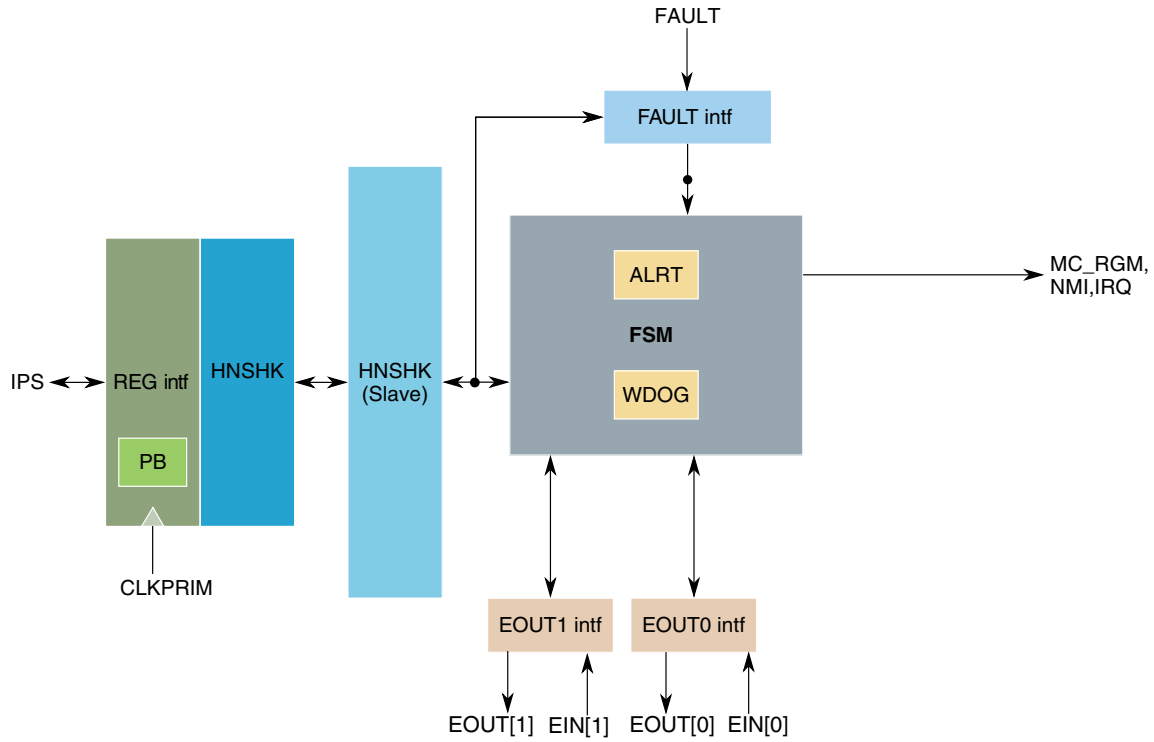

Figure 208. FCCU block diagram

This table describes the FCCU submodules.

Table 295. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSM ability to support the handshake between the REG interface and the FSM unit because of the usage of two asynchronous clocks [CLKPRIM(module clock) and CLKSAFE(RC oscillator clock)]
FSM unit	Implements the main functions of FCCU. The FSM also includes the: • Watchdog timer (WDG) • Alarm timer (ALRT)
FAULT intf	Implements the interface for fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

52.2.2 Features

The key features of the FCCU module are these:

- Management of non-critical faults
- HW or SW fault recovery management
- Fault collection from safety relevant modules on the device

- Fault injection (fake faults)
- Collection of test results
- Lockable configuration
  - Changes are only possible after entering the CONFIG state
  - Supports a transient and a permanent lock
  - Configuration changes observed by a watchdog timer
- Configurable fault control
- External reaction (FAULT state): EOUT signaling. Error indication via the pin(s) is controlled by FCCU.
- Internal chip reactions (ALARM state): interrupt request
- Configurable internal chip reactions for each NCF (FAULT state):
  - Short functional reset request pulse
  - NMI
  - No reaction
  - IRQ
- In Bi-Stable operational mode, one of the EOUT signals is high to indicate an OK operational state of FCCU.
- After power on, the EOUT signals have high impedance.[11] They indicate an operational state only after the software configures them.
- In case of a failure event or on software request for error pin indication, the pin(s) are set to faulty state for a minimum time T_{min} (see DELTA_T[DELTA_T]), even if the software tries to release it before (for the case of error pin configured in Bi-Stable mode only).

The self-checking procedure checks the FCCU circuitry at the start up. The FCCU is operational with the default configuration immediately after the completion of the self-checking procedure. Internal (short functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the Configuration (CONFIG) state. FCCU is designed to function when CLKPRIM is faster than the CLKSAFE clocks.

52.3 Functional description

52.3.1 Definitions

In general, the following definitions are applicable for fault management:

- HW recoverable fault: The fault indication is a level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: The fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error sources by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition is corrected.

For details related to reset interface, see the reset interface section in the chip reference manual.

52.3.2 FSM description

The functionality of FCCU is depicted by the FSM state diagram (see Figure 209).

[11] Actual value depends on device-specific setting at pad level.

FCCU has four states that are identified with the following meaning:

- CONFIG: Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, non-critical fault masking) can be accessed in write mode only in the CONFIG state.

  The CONFIG state is accessible only in the NORMAL state and if the configuration is not locked. A permanent configuration lock can be disabled by a reset that also resets the FCCU. The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into TRANS_LOCK[TRANSKEY] (that is, other than BCh). To lock FCCU for configuration, write FFh to PERMNT_LOCK[PERMNTKEY].

  After the release of reset, the state of the transient lock is locked, and the state of the permanent lock is unlocked.

  The locking feature only restricts the FSM movement into CONFIG state. After the user enters the CONFIG state and then tries to lock the configuration, the locking of configuration is effective only after FCCU moves to the NORMAL state; it will not be effective in the current CONFIG state.

  The CONFIG to NORMAL state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request for state change to NORMAL appears at the same time, watchdog timeout has the priority and hence the configuration registers (those that are writable only in the CONFIG state) are reset to their default values. The movement to the NORMAL state is made.

  The incoming faults, occurring during the configuration phase (CONFIG state) are latched in order to process them when FCCU is moved to the NORMAL state, according to the new configuration.

  All pending faults that occur during the CONFIG state result in both of the following:

  — Highest-priority state transition

  — Interrupt generation (NMI or alarm IRQ)

  If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or non-pending faults) that occurred during the CONFIG state.

- NORMAL: This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:

  — Unmasked non-critical faults with the timeout disabled: FCCU moves to the FAULT state.

  — Unmasked non-critical faults with the timeout enabled: FCCU moves to the ALARM state.

  — Masked non-critical faults: FCCU stays in the NORMAL state.

- ALARM: FCCU moves into the ALARM state when an unmasked non-critical fault occurs and the timeout is enabled. Transition to the ALARM state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to the FAULT state. The timeout is reinitialized if FCCU enters the NORMAL state. The timeout restarts following the recovery from the FAULT state.
- FAULT: FCCU moves into the FAULT state when one of the following condition occurs:

  — Timeout related to a non-critical fault when FCCU is in the ALARM state

  — Unmasked non-critical faults with the timeout disabled

The transition from the NORMAL or ALARM to the FAULT state goes along with the generation of:

- Internal chip reaction—NMI interrupt (optional)
- External reaction—EOUT signaling (optional)
- Internal chip reaction—SW option: Soft reaction (Short functional reset request pulse if configured)
- Non Maskable Interrupt (NMI) is routed to all cores.

After moving to the FAULT state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time.

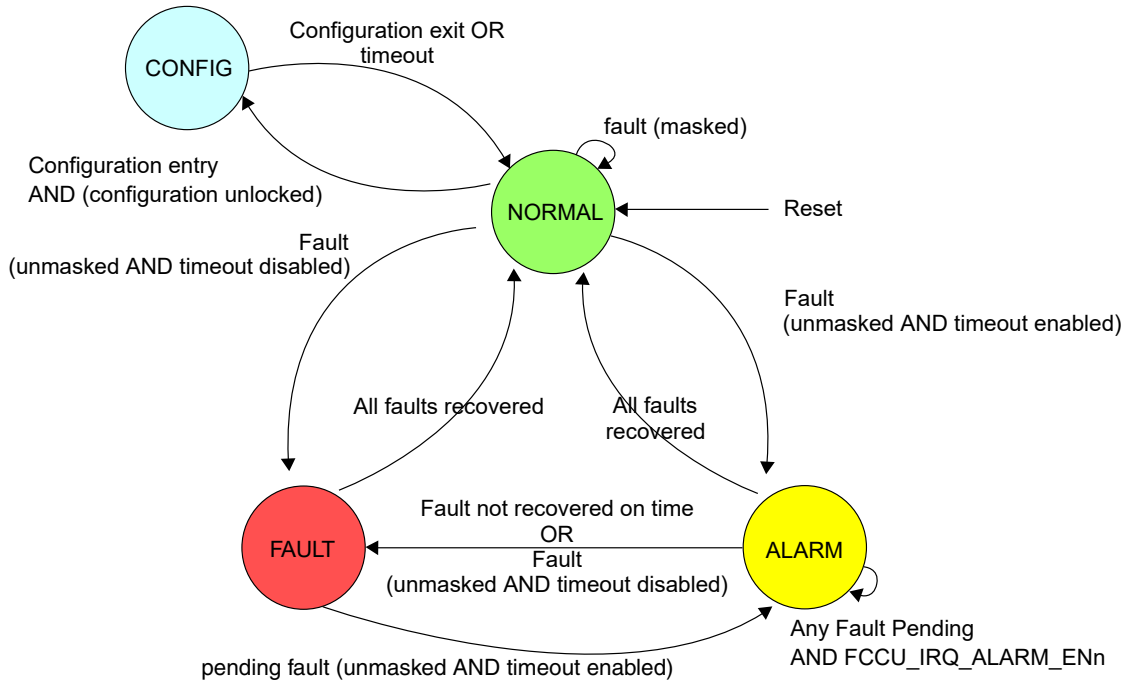

Figure 209. FCCU state diagram

52.3.3 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (non-critical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a non-critical fault (unmasked and with timeout disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU remains in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU moves to the ALARM state (if any non-critical fault is still pending and the timeout is not elapsed).

In general, no fault nesting is supported except for the non-critical faults that cause an ALARM to FAULT state transition. In this case, the NCF timer is stopped until the FAULT state is recovered. If FCCU is in the ALARM state and another fault occurs, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

52.3.4 Fault recovery

The following timing diagrams describe the main use cases of FCCU in terms of fault events and related recovery.

A typical sequence related to non-critical fault management (ALARM state), see Figure 210 and Figure 211, is as follows:

1. Non-critical fault assertion
2. FCCU state transition (automatic): NORMAL to ALARM
   - Alarm interrupt request (if enabled)
   - Timeout running
3. System state: RUN
4. Alarm interrupt management: fault recovery

- FCCU state transition: ALARM to NORMAL

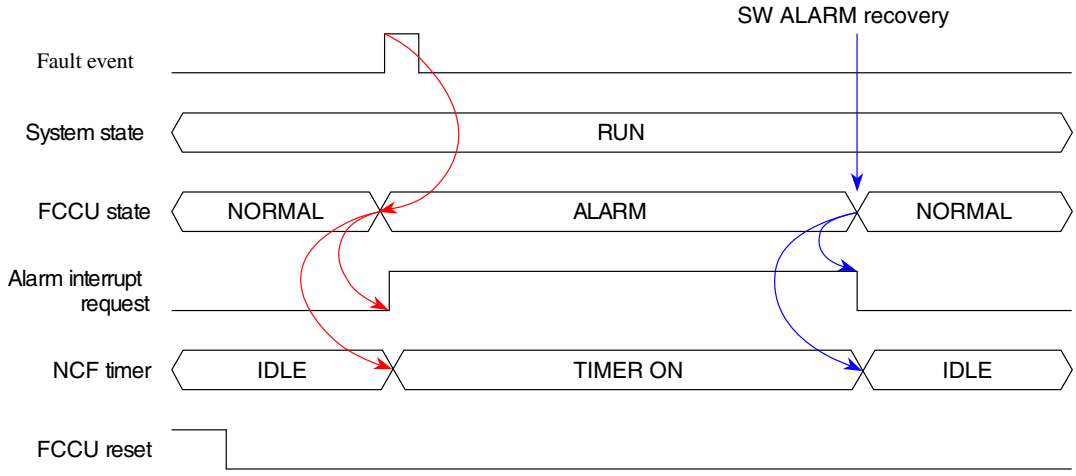

Figure 210. Non-critical fault (ALARM state) SW recovery

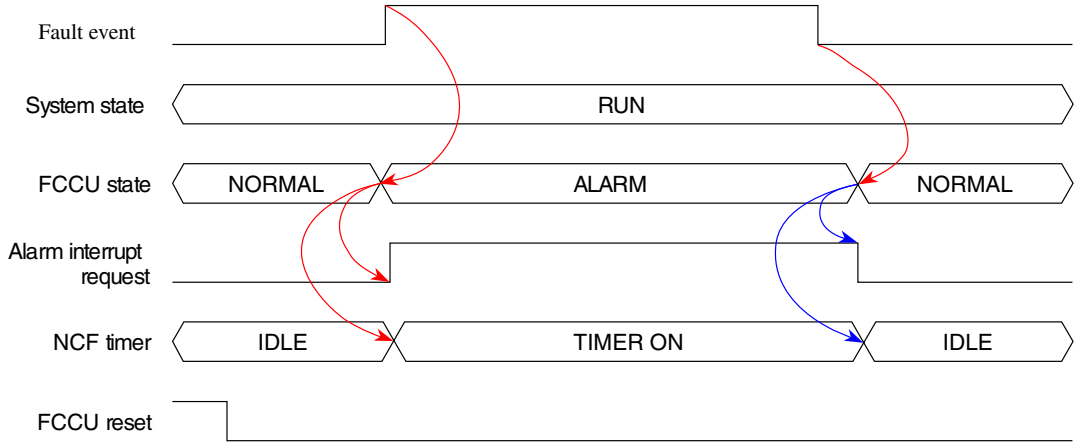

Figure 211. Non-critical fault (ALARM state) HW recovery

A typical sequence related to non-critical fault management (ALARM to FAULT state), see Figure 212, is as follows:

1. Non-critical fault assertion
2. FCCU state transition (automatic): NORMAL to ALARM
   - Alarm interrupt request (if enabled)
   - Timeout running
3. FCCU state transition (following the timeout trigger): ALARM to FAULT
   - NMI assertion (if enabled)
4. NMI interrupt management (if enabled)
   - Fault recovery (by software): FCCU state transition: FAULT to NORMAL

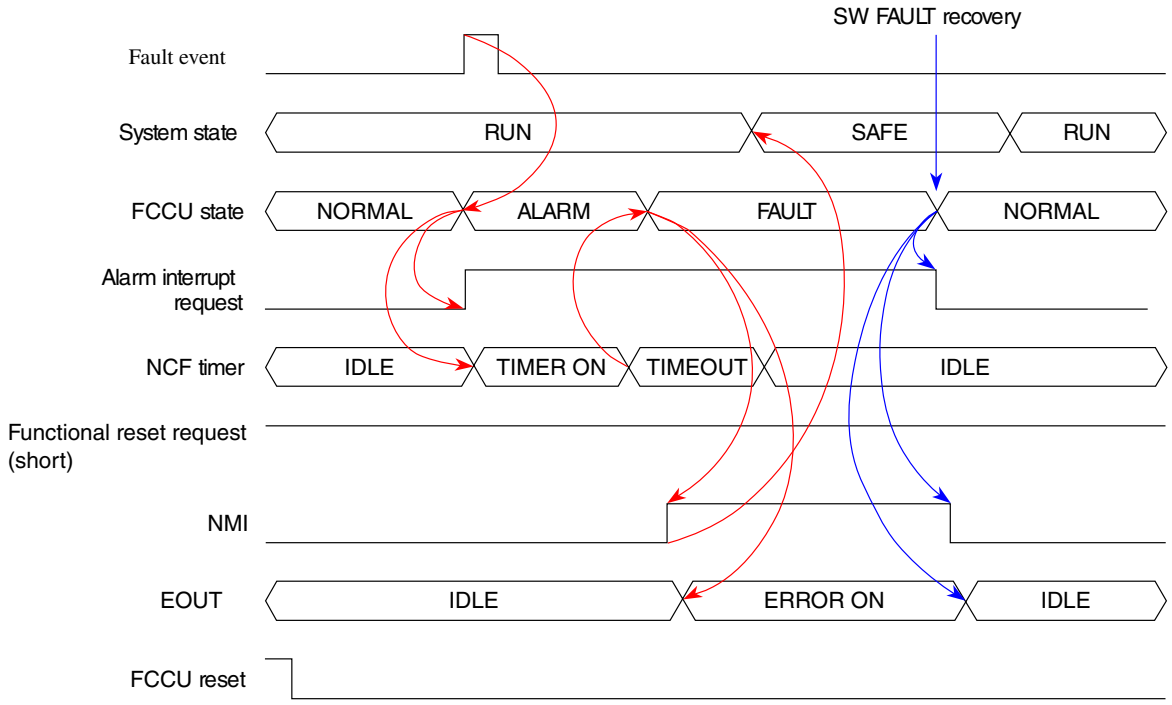

Figure 212. Non-critical fault (ALARM to FAULT state) recovery

52.3.5 EOUT interface

Introduction

You use the EOUT[1:0] signals to indicate FCCU's condition (or, for Fault-Toggle fault-output mode, faults only) to off-chip logic.

NOTE

For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

The FCCU conditions

There are three FCCU conditions:

Condition	Description
Faulty	All of the following are true: • The fault-output (EOUT) timer is running (see How the fault-output (EOUT) timer works in Bi-Stable fault-output mode). • FCCU is in FAULT state.
Non-faulty	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in ALARM or NORMAL state.

Table continues on the next page...

Table continued from the previous page...

Condition	Description
Configuration	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in CONFIG state.

How the fault-output (EOUT) timer works in Bi-Stable fault-output mode

In Bi-Stable fault-output mode (FOM), FCCU starts the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bi-Stable FOM, and the EOUT signals are not programmed to be always low (CFG[FCCU_SET_CLEAR]).
- The EOUT timer is not already running.
- FCCU enters the FAULT state as the result of a fault.

When the fault-output (EOUT) timer is already running and a new fault occurs:

- If FCCU is in the CONFIG state: FCCU does not restart the EOUT timer.
- If FCCU is in the NORMAL or ALARM state:
  - And ALARM state is enabled for the fault (non-critical): FCCU enters (or remains in) the ALARM state but does not restart the EOUT timer.
  - And ALARM state is disabled for the fault (non-critical): FCCU enters the FAULT state and restarts the EOUT timer.
- If FCCU is in the FAULT state: FCCU restarts the fault-output (EOUT) timer.

FCCU stops and reinitializes the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bi-Stable fault-output mode (CFG[FOM]), and T_{min} (see DELTA_T[DELTA_T]) has expired.
- All faults that caused FCCU to enter or remain in the FAULT state since FCCU started the fault-output (EOUT) timer have been cleared, causing FCCU to return to the NORMAL state.

How the fault-output (EOUT) timer works in Fault-Toggle fault-output mode

In Fault-Toggle fault-output mode, FCCU initializes the fault-output (EOUT) timer with the value of T_{min} (see DELTA_T[DELTA_T]) and begins decrementing the timer when any of the following are true:

- FCCU enters the FAULT state as the result of a fault.
- In FAULT state, a fault occurs while the EOUT timer is 0 (idle).
- In FAULT state, a fault occurs while the EOUT timer is running because of a previous fault (also called a pending fault), and then in any state the EOUT timer reaches 0 (idle).

FCCU stops the EOUT timer when it reaches 0 (idle).

Prepare the EOUT signals to indicate FCCU's condition

- If the EOUT signals are in Bi-Stable or Fault-Toggle fault-output mode (CFG[FOM]), ensure that the EOUT signals are controlled by FCCU's FSM (CFG[FCCU_SET_CLEAR]).
- Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]).

NOTE

If the EOUT signals are in Bi-Stable or Fault-Toggle fault-output mode, you must deactivate and then reactivate the EOUT signals (CFG[FCCU_SET_AFTER_RESET]) to correctly initialize them so they have opposite states.

More about the EOUT interface

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported (CFG[FOM]):

- Bi-Stable
- Fault-Toggle

NOTE

See the chip-specific FCCU information for the fault-output modes supported by this chip.

You can further configure the fault-output modes using the following attributes:

Attribute	Field	Setting used in the example diagrams and tables that follow
Configuration mode	CFG[CM]	Different
Polarity selection	CFG[PS]	For the faulty indication, EOUT1 is high, and EOUT0 is low.

EOUT frequency: This frequency is generated by dividing the CLKSAFE frequency by a fixed factor of 2^{18}.

$$EOUT_{freq} = \frac{CLKSAFE_{freq}}{2^{18}}$$

For example, with a CLKSAFE frequency of 16 MHz, this drives a signal of 61 Hz on EOUT.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time (T_{min}), even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK, such as an incoming fault is not masked even when software has set the error signal to high. Also, if the error signals are forced to low by software by writing to CFG[FCCU_SET_CLEAR], then the signals shall remain low (or high) for the entire duration of T_{min}. During the T_{min} by a non-software fault, the FCCU FSM moves independently of this signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to the CONFIG state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the T_{min} interval to expire, after which the FCCU automatically enters the NORMAL state and the error signal indicates OK.

In case another failure event happens within T_{min} after a first one, the T_{min} counter is restarted.

52.3.5.1 Bi-Stable protocol

The encoding scheme is provided in Table 296 and the related timing diagram is shown in Figure 213.

Table 296. Bi-Stable encoding

Condition	EOUT[1:0] (CFG[PS] is 0)	EOUT[1:0] (CFG[PS] is 1)
Non-faulty	Static 01	Static 10
Faulty	Static 10	Static 01

Table continues on the next page...

Table 296. Bi-Stable encoding (continued)

Condition	EOUT[1:0] (CFG[PS] is 0)	EOUT[1:0] (CFG[PS] is 1)
Reset	High-impedance (no toggling)[1]	High-impedance (no toggling)
Configuration (CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 0)	High-impedance (no toggling)[2]	High-impedance (no toggling)
Configuration (When CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 1)	Static 01	Static 10

1. Final value depends on device specific settings at pad level.
2. Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]); otherwise, the EOUT signals stay in a high-impedance state after reset lifts.

NOTE

Figure 213 is formatted to display the behavior in all four conditions (reset, non-faulty, faulty, and configuration), not to imply transitions between one condition and another. In particular, a transition from the faulty condition to the configuration condition is not possible.

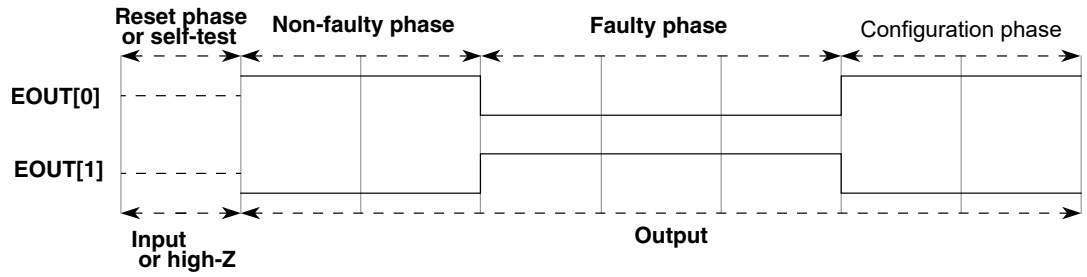

Figure 213. Bi-Stable protocol

52.3.5.2 Fault-Toggle protocol

The Fault-Toggle protocol uses the EOUT signals to indicate only the occurrences of faults, not FCCU's condition like the other protocols. In Fault-Toggle fault-output mode, when controlled by the FSM (CFG[FCCU_SET_CLEAR]), the EOUT signals:

- Have opposite states
- Toggle their states to indicate a fault and then maintain those new states for at least T_{min} (see DELTA_T[DELTA_T]), after which they are free to toggle to indicate another fault

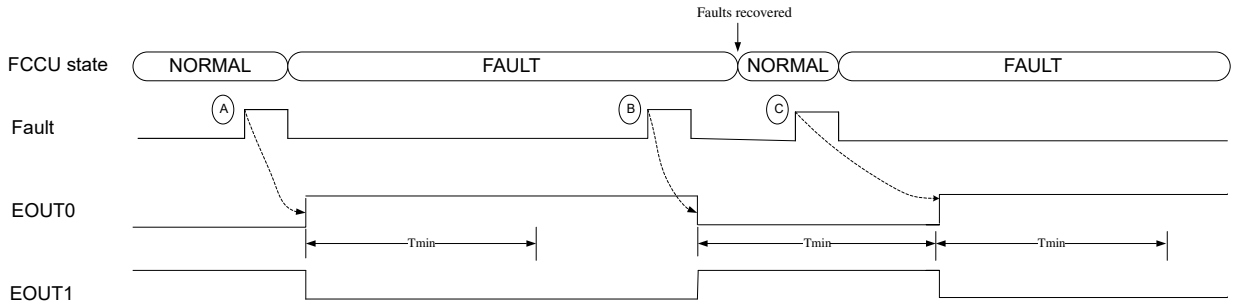
FCCU uses the fault-output (EOUT) timer to measure T_{min}. For more information, see How the fault-output (EOUT) timer works in Fault-Toggle fault-output mode.

The EOUT polarity selection (CFG[PS]) determines the initial states of the EOUT signals, which FCCU applies after you deactivate and then reactivate the EOUT signals (CFG[FCCU_SET_AFTER_RESET]).

If two or more faults occur while the EOUT timer is running, then the EOUT signals toggle only once after the EOUT timer reaches zero (idle). In other words, FCCU can pipeline only one fault.

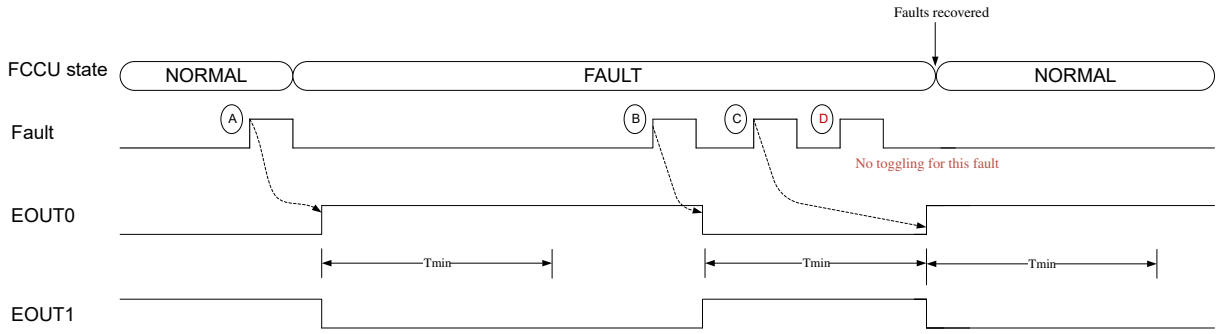
Note that FCCU does not toggle the EOUT signals in CONFIG state. FCCU toggles the EOUT signals only when FCCU enters the FAULT state or when a fault occurs in the FAULT state.

Example 1



Stage	Description
1	A fault source indicates fault A to FCCU.
2	FCCU enters the FAULT state.
3	FCCU toggles the EOUT signals in response to fault A, initializes the fault-output (EOUT) timer with the value of T_{min} (see DELTA_T[DELTA_T]), and begins decrementing the timer.
4	A fault source indicates fault B to FCCU while FCCU is still in the FAULT state.
5	The EOUT timer has already reached 0 (idle), so FCCU toggles the EOUT signals in response to fault B, initializes the EOUT timer with the value of T_{min}, and begins decrementing the timer.
6	The source (for hardware-recoverable faults) and software (for software-recoverable faults) recovers the faults.
7	FCCU enters the NORMAL state.
8	A fault source indicates fault C to FCCU.
9	The EOUT timer has not yet reached 0 (idle), so FCCU leaves the EOUT signals as they are.
10	When the EOUT timer reaches 0 (idle), FCCU toggles the EOUT signals in response to fault C, initializes the EOUT timer with the value of T_{min}, and begins decrementing the timer.

Example 2



Stage	Description
1	A fault source indicates fault A to FCCU.
2	FCCU enters the FAULT state.
3	FCCU toggles the EOUT signals in response to fault A, initializes the fault-output (EOUT) timer with the value of T_{min} (see DELTA_T[DELTA_T]), and begins decrementing the timer.
4	A fault source indicates fault B to FCCU while FCCU is still in the FAULT state.
5	The EOUT timer has already reached 0 (idle), so FCCU toggles the EOUT signals in response to fault B, initializes the EOUT timer with the value of T_{min}, and begins decrementing the timer.
6	A fault source indicates fault C to FCCU while FCCU is still in the FAULT state.
7	The EOUT timer has not yet reached 0 (idle), so FCCU leaves the EOUT signals as they are. Fault C is now *pending*.
8	A fault source indicates fault D to FCCU while FCCU is still in the FAULT state. (FCCU can pipeline only one fault, so FCCU ignores fault D.)
9	The EOUT timer has not yet reached 0 (idle), so FCCU leaves the EOUT signals as they are.
10	When the EOUT timer reaches 0 (idle), FCCU toggles the EOUT signals in response to fault C, initializes the EOUT timer with the value of T_{min}, and begins decrementing the timer. FCCU never toggles the EOUT signals in response to fault D because FCCU can pipeline only one fault.

52.3.6 Modes of operation

52.3.6.1 Put FCCU in the NORMAL state

52.3.6.1.1 Introduction

You put FCCU in the NORMAL state to save changes to the configuration, and to allow FCCU to enter the ALARM or FAULT state when a fault occurs on an enabled fault channel.

52.3.6.1.2 About putting FCCU in NORMAL state

When putting FCCU in the NORMAL state:

- If you attempt to lock the configuration while FCCU is in CONFIG state, FCCU does not actually lock the configuration until FCCU leaves CONFIG state—that is, either you put FCCU in the NORMAL state, or FCCU puts itself in the NORMAL state because the Configuration-state timeout interval (CFG_TO[TO]) expires.
- After you permanently lock the configuration, you must reset FCCU before you can put FCCU in the CONFIG state.

52.3.6.1.3 Put FCCU in the NORMAL state

1. Check the FCCU status (STAT[STATUS]).
   - If the FCCU status is NORMAL, go to step 6.
   - If the FCCU status is CONFIG, go to step 2.
   - If the FCCU status is ALARM or FAULT, go to step 4.
2. Run the OP2 operation (see Run an operation).
3. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, FCCU is in the NORMAL state. Go to step 6.
   - If the operation status is Aborted, go to step 2.
4. Recover all faults (see Fault recovery).
5. Go to step 1.
6. Lock the configuration if you want to prevent any changes to it:
   - To require a key to unlock the configuration, from Supervisor mode, temporarily lock the configuration (TRANS_LOCK[TRANSKEY]).
   - To require a reset of FCCU to unlock the configuration, from Supervisor mode, permanently lock the configuration (PERMNT_LOCK[PERMNTKEY]).

     The configuration is permanently locked until FCCU is reset.

52.3.6.2 Manage faults

52.3.6.2.1 Introduction

After saving changes to the configuration, you are ready to use FCCU to manage faults.

52.3.6.2.2 Determine if there are any unrecovered non-critical faults

Check the unrecovered-fault indicators for the non-critical faults (NCF_Sa[NCFSn]).

52.3.6.2.3 Recover a software-recoverable non-critical fault

1. Resolve the source of the software-recoverable non-critical fault.
2. Unlock the NCF_Sa registers (NCFK[NCFK]) using a 32-bit write.

3. Initiate clearing of the unrecovered-fault indicator for the software-recoverable non-critical fault (NCF_Sa[NCFSn]) using a 32-bit write.

   FCCU initiates the OP12 operation.

   NOTE

   If you want to clear multiple unrecovered-fault indicators and those indicators reside in different NCF_Sa registers, you must perform steps 2 and 3 for each individual register.

4. Check the operation status (CTRL[OPS]).
   - If the operation status is In Progress, go to step 4.
   - If the operation status is Successful, go to step 5.
   - If the operation status is Aborted, go to step 2.
5. Check the unrecovered-fault indicator for the software-recoverable non-critical fault (NCF_Sa[NCFSn]).
   - If the indicator indicates no unrecovered fault, the fault has been recovered. Stop.
   - If the indicator still indicates an unrecovered fault, go to step 2.

52.3.6.2.4 Clear the freeze-status indicators

1. Run the OP13 operation (see Run an operation).
2. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, stop .
   - If the operation status is Aborted, go to step 1.

52.3.6.3 Run operations

52.3.6.3.1 Introduction

You run operations to perform actions such as putting FCCU in the CONFIG state or setting the operation status to Idle. For a complete list of operations you can run, see CTRL[OPR].

52.3.6.3.2 About running operations

When running operations:

- FCCU ignores any operations initiated while the operation status is In Progress.
- Certain operations must be unlocked before you can initiate them. After you initiate them, they are locked again.

52.3.6.3.3 Run an operation

1. Check the operation status (CTRL[OPS]).
2. Go to step 1 if the operation status is In Progress.
3. Unlock the operation (CTRLK[CTRLK]) using a 32-bit write, if the operation must be unlocked before you can initiate it.

   NOTE

   The Control Key (CTRLK) register used in this step and the Control (CTRL) register used in the next step must be written with consecutive instructions. Do not use read-modify-write instructions, such as bit-field instructions, to modify these registers.

4. Initiate the operation (CTRL[OPR]) using a 32-bit write.
5. Check the operation status (CTRL[OPS]).

6. Go to step 5 if the operation status is In Progress.

The operation status is now Idle (OP15 only), Aborted, or Successful.

52.3.7 FOSU

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU's behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from FCCU which indicates that the FCCU is programmed for no reaction for ALL FAULTS. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted (that is, a disabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during the CONFIG state.

The FOSU contains a timer with a duration of FOSU_COUNT, driven by CLKSAFE. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FOSU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: short functional reset
- IRQ (triggered by ALARM state)
- NMI
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared to ensure that the timer is not restarted because of faults still 'stuck' in the capture logic. The timer is then restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC_RGM's 'destructive' reset inputs, so its assertion will cause a reset sequence to be initiated starting at DEST0. The FOSU module is reset with the same reset as is used by the FCCU. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

NOTE

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times out without reaction.

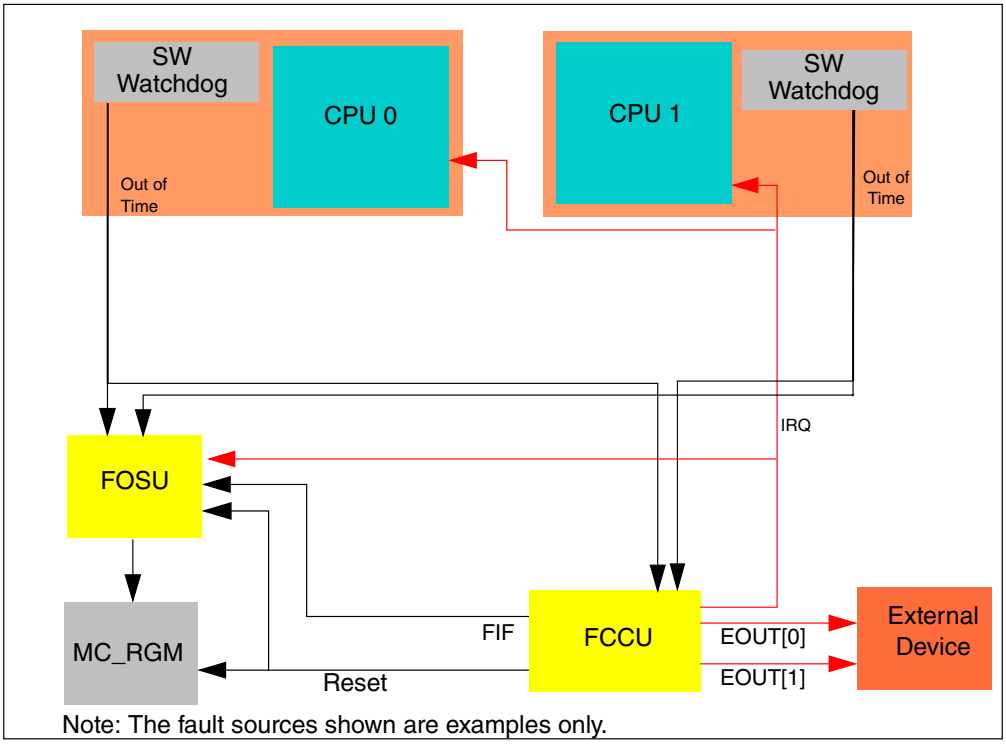


Figure 214. FOSU connections to the FCCU and MC_RGM

52.3.8 Clocking

This module has no clocking considerations.

52.3.9 Interrupts

This module has no interrupts.

52.4 External signals

FCCU interfaces with the EOUT pin. Signaling on the EOUT pin depends on whether the module is processing an error or is idle.

52.5 Initialization

52.5.1 Prepare FCCU for configuration

52.5.1.1 Introduction

You prepare FCCU for configuration by first configuring the CONFIG state and then putting FCCU in that state.

52.5.1.2 About preparing FCCU for configuration

When preparing FCCU for configuration, keep the following in mind:

- To put FCCU in CONFIG state, FCCU must be in NORMAL state.
- After FCCU is reset, the configuration is temporarily locked. You must temporarily unlock the configuration before you can put FCCU in the CONFIG state.

- When FCCU is in the CONFIG state, FCCU does not actually save the changes you make to the configuration. To save changes to the configuration, you must manually put FCCU in the NORMAL state. If FCCU automatically leaves the CONFIG state and enters the NORMAL state because the Configuration-state timeout interval (CFG_TO[TO]) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. FCCU also changes the value of the Configuration-State Timeout Interval (CFG_TO) register to its reset value. For information on the Configuration-state timeout value, see CFG register bit value at different events. For a list of configuration registers, see Configuration registers.

52.5.1.3 Configure the CONFIG state

1. Set the Configuration-state timeout interval (CFG_TO[TO]).
2. Enable the Configuration-state-timeout interrupt signal (IRQ_EN[CFG_TO_IEN]), if you want FCCU to request an interrupt when a Configuration-state timeout occurs.

52.5.1.4 Put FCCU in the CONFIG state

1. Unlock the configuration temporarily (TRANS_LOCK[TRANSKEY]) in Supervisor mode.
2. Check the FCCU status (STAT[STATUS]).
   - If the FCCU status is CONFIG, FCCU is in the CONFIG state. Stop.
   - If the FCCU status is NORMAL, go to step 3.
   - If the FCCU status is ALARM or FAULT, go to step 5.
3. Run the OP1 operation (see Run an operation).
4. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, FCCU is in the CONFIG state. Stop.
   - If the operation status is Aborted, the configuration is probably permanently locked. Go to step 7.
5. Recover all faults (see Fault recovery).
6. Go to step 2.
7. Reset FCCU.

52.5.2 Configure FCCU

52.5.2.1 Introduction

You configure FCCU so it functions according to the needs of your particular application.

52.5.2.2 About configuring FCCU

When configuring FCCU:

- If you enable a non-critical fault channel but disable all reactions for that channel, FCCU changes state when necessary but does not perform any reaction because reactions are disabled. If you enable reactions for a non-critical fault channel but disable that channel, and FCCU is in the NORMAL state when a fault occurs on the channel, FCCU does not enter the ALARM or FAULT state and therefore does not perform any reaction.

52.5.2.3 Configure the non-critical fault channels

For each non-critical fault channel that you want FCCU to monitor:

1. Set the recovery type (NCF_CFGa[NCFCn]).
2. Enable at least one type of Fault-state reaction:
   - Chip functional reset (NCFS_CFGa[NCFSCn])

- Non-maskable interrupt (NMI_ENa[NMIENn])
- EOUT signaling (EOUT_SIG_ENa[EOUTENn])

NOTE

If you enable the chip functional reset as the type of Fault-state reaction for a channel, enable at least one other type of Fault-state reaction for the channel or enable the ALARM state (step 4) for the channel.

3. Set the Alarm-state timeout interval (NCF_TO[TO]), if you plan to enable the ALARM state for any non-critical fault channel.

NOTE

Ensure that the Alarm-state timeout interval is less than the FOSU module's timeout interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timeout interval (FOSU_COUNT) is a chip-specific value. See the chip-specific FCCU information.

4. Enable the ALARM state (NCF_TOEa[NCFTOEn]) for any non-critical fault channel for which you want FCCU to enter the ALARM state before entering the FAULT state.
5. Enable the Alarm-state reaction (IRQ_ALARM_ENa[IRQENn]) for each non-critical fault channel for which you enabled the ALARM state.
6. Enable the corresponding NCF_Ea[NCFEn] field for each non-critical fault channel that you want FCCU to monitor.

52.6 Application information

52.6.1 Use cases and limitations

Configuration guidelines

Follow these guidelines to configure FCCU:

- If you want FCCU to react to a fault on a non-critical fault channel:
  - Enable the channel (Non-critical Fault Enable (NCF_E0)).
  - Enable at least one type of Fault-state reaction for the channel: chip reset (Non-critical Fault-State Configuration (NCFS_CFG0)), fault-output (EOUT) signaling (Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)), or non-maskable interrupt (Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)).
  - If you enable chip reset as the type of Fault-state reaction for the channel (Non-critical Fault-State Configuration (NCFS_CFG0)), enable either ALARM state (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)) or at least one other type of Fault-state reaction for the channel: fault-output (EOUT) signaling (Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)) or non-maskable interrupt (Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)).
  - If you enable ALARM state for the channel (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)), enable the Alarm-state reaction (Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0)).
  - If you enable ALARM state for the channel (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)), make sure the Alarm-state timer interval (Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)) is less than the FOSU module's timer interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timer interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

Recommendations to configure FCCU

1. After a power on, or 'destructive' reset (when initiated by the assertion of the chip reset pin, RESET_B), where both system and FCCU are reset, the following steps could be followed to configure FCCU:
   a. Check and clear any pending fault status
   b. Verify FCCU is in NORMAL state, else repeat step(a) above

c. Configure FCCU

2. After any 'functional' reset of the system, arising out of a reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a. If active, wait for the Error out T_{min} to expire
   b. Check and clear fault status
   c. Error pin moves to "non faulty" state, once fault status is cleared and T_{min} expires
   d. Verify FCCU is in NORMAL state, else repeat step(a) above
   e. Read and verify value in NCF_En
   f. Reconfigure FCCU, if necessary

52.7 Register descriptions

52.7.1 FCCU register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Do not read from or write to any addresses that are not shown in the following table. Doing so may or may not result in a transfer error.
- Do not write to any of the configuration registers unless FCCU is in the CONFIG state. Doing so results in a transfer error.
- Do not write to the Transient Configuration Lock (TRANS_LOCK) or Permanent Configuration Lock (PERMNT_LOCK) registers unless your code runs in the Supervisor mode. Doing so results in a transfer error.

For each possible NCF failure source, a different reaction—including no reaction—is configurable through the use of NMI, IRQ, and short reset selection registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

52.7.1.1 FCCU memory map

52.7.1.2 Control (CTRL)

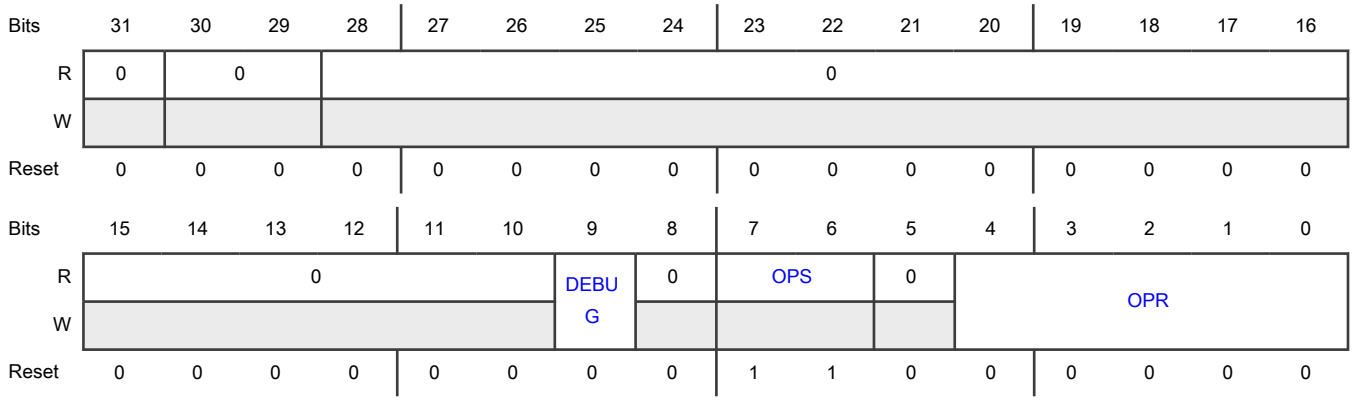
Offset

Register	Offset
CTRL	0h

Function

Initiates and indicates the status of operations—and enables the Debug mode.

Diagram



Fields

Field	Function
31 —	Reserved
30-29 —	Reserved
28-10 —	Reserved
9 DEBUG	Debug Mode Enable Specifies whether the Debug mode is enabled. If so, FCCU enters the Debug mode when the Debug signal is asserted. When FCCU enters the Debug mode, it halts operation and remains in the state it was in before it entered this mode. **NOTE** FOSU does not halt when FCCU enters the Debug mode. Therefore, FOSU can still cause a reset if a fault occurs while FCCU is in the Debug mode. 0b - Disabled 1b - Enabled
8 —	Reserved
7-6 OPS	Operation Status This field can be read and cleared (via OP15 operation) by the software. 00b - Idle 01b - In progress 10b - Aborted

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Successful
5 —	Reserved
4-0 OPR	Operation Run Initiates operations that perform actions such as putting FCCU in the CONFIG state or setting the operation status to Idle. For information on how to run operations, see Run operations. FCCU ignores any write to this field while the operation status (CTRL[OPS]) is "In progress". After completion of an operation, FCCU sets this field to OP0. The following events result in an operation status (CTRL[OPS]) of "Aborted": • Writing to a NCF_Sa register (which automatically initiates the OP12 operation) without first successfully unlocking the register (NCFK[NCFK]) • Initiating an OP1 operation when FCCU is not in the NORMAL state or the configuration is locked • Initiating an OP1, or OP2, operation without first unlocking the operation (CTRLK[CTRLK]) 00000 OP0—No operation 00001 OP1—Applies only when the configuration is unlocked, when FCCU is in the NORMAL state, and immediately after you unlock the operation (CTRLK[CTRLK]). Put FCCU in the CONFIG state. 00010 OP2—Applies only immediately after you unlock the operation (CTRLK[CTRLK]). Put FCCU in the NORMAL state. 00011 Reserved 00100 Reserved 00101 Reserved 00110 Reserved 00111 Reserved 01000 Reserved 01001 Reserved 01010 Reserved 01011 Reserved 01100 OP12—Do not initiate this operation; it is automatically initiated by the FCCU. A NCF_Sa register status clear operation is in progress. 01101 OP13—Clear the freeze status registers. 01110 OP14—Do not initiate this operation; it is automatically initiated by the FCCU. A Configuration-state timeout is in progress. For more information, see Configuration registers. 01111 OP15—Set the operation status (CTRL[OPS]) to Idle. 10000 Reserved 10001 Reserved

Table continues on the next page...

Table continued from the previous page...

Fields

Field	Function
31-0 CTRLK	Locked-Operation Control Key Writable only with a 32-bit write. Unlocks locked operations (CTRL[OPR]) so you can initiate them. For information on how to unlock locked operations before you initiate them, see Run an operation.

Table continues on the next page...

Field	Function
	NOTE • You must initiate an operation in the FCCU register access that immediately follows the one that unlocks it; otherwise, the operation is again locked. • Reading from this register always returns the value 0000_0000h. Operations not listed here are not locked and do not need to be unlocked. 9137_56AFh: Unlock OP1. 825A_132Bh: Unlock OP2. Any other value: Do nothing.

52.7.1.4 Configuration (CFG)

Offset

Register	Offset
CFG	8h

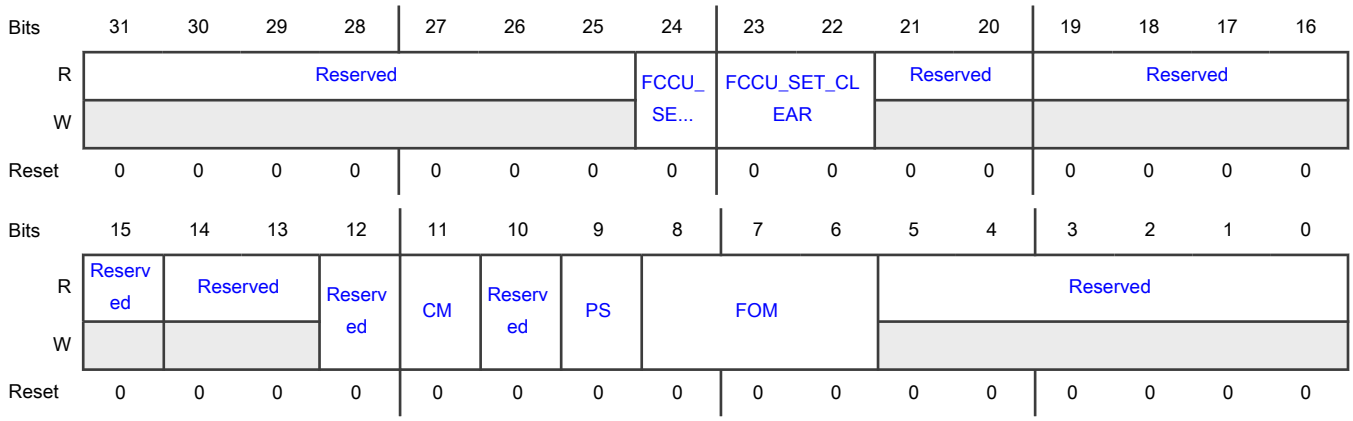
Function

Writable only when FCCU is in the CONFIG state. Changed by FCCU to another value when the chip resets FCCU, a Configuration-state timeout occurs, or you run an OP31 operation. See CFG register bit value at different events for more information. Specifies the global configuration for FCCU.

NOTE

If you specify a new value for any of the fields in this register that affect the EOUT signals while the fault-output (EOUT) timer is running (FCCU is indicating a fault on the EOUT signals), FCCU does not use the new settings you specified until after the fault-output (EOUT) timer expires (FCCU stops indicating a fault on the EOUT signals).

Diagram



Fields

Field	Function
31-25 —	Reserved
24 FCCU_SET_AFTER_RESET	Fault-Output (EOUT) Activate For fault-output (EOUT) signaling, controls whether the EOUT signals are active. 0b - Inactive (the EOUT signals are in a high-impedance state) 1b - Active (the EOUT signals indicate FCCU's condition)
23-22 FCCU_SET_CLEAR	Fault-Output (EOUT) Control Applies only to Bi-Stable and Fault-Toggle fault-output modes (CFG[FOM]) and when the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]). Controls whether the fault-output (EOUT) signals are managed by FCCU's FSM. **NOTE** When the EOUT signals are in the Fault-Toggle fault-output mode, if you change the value of this field, you must also deactivate and then reactivate the EOUT signals (CFG[FCCU_SET_AFTER_RESET]) to correctly initialize them so they have opposite states. 00b - Controlled by the FSM 01b - Always low 10b - Controlled by the FSM 11b - High until a fault occurs on a channel, regardless of whether that fault is disabled; thereafter, controlled by the FSM. Note: FCCU ignores an attempt to write this value if the fault-output (EOUT) timer is already running.
21-20 —	Reserved
19-16 —	Reserved
15 —	Reserved
14-13 —	Reserved

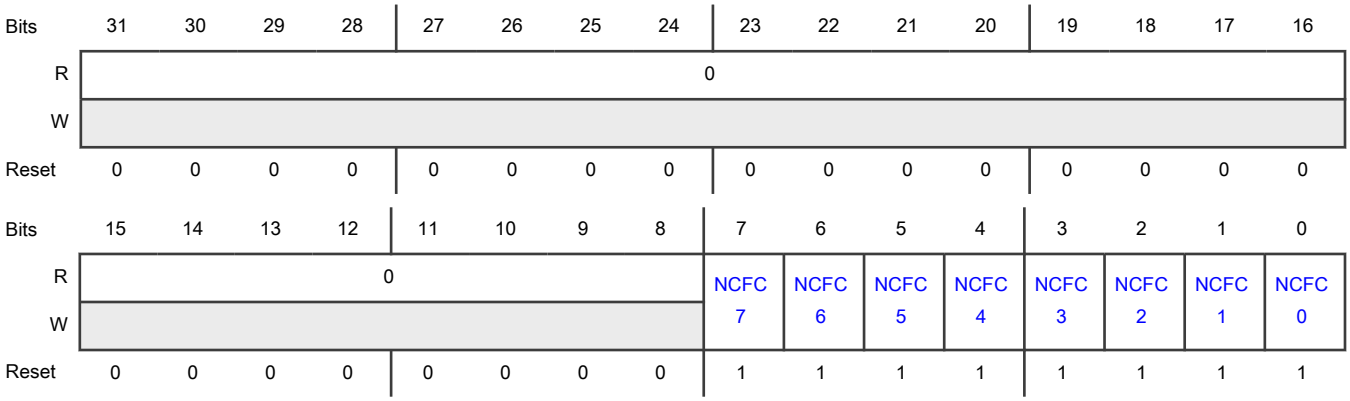
Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 NCFTOEn	Non-critical-Fault Alarm-State Timeout Enable n Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Controls whether the ALARM state is enabled for the associated non-critical fault channel (n). When the ALARM state is enabled for an enabled non-critical fault channel, a fault on that channel causes FCCU to leave the NORMAL state and enter the ALARM state instead of FAULT state. If the fault is not recovered within the Alarm-state timeout interval, then FCCU leaves the ALARM state and enters the FAULT state. For information on how to configure the non-critical fault channels, see Configure the non-critical fault channels. 0b - Disabled 1b - Enabled

52.7.1.11 Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)

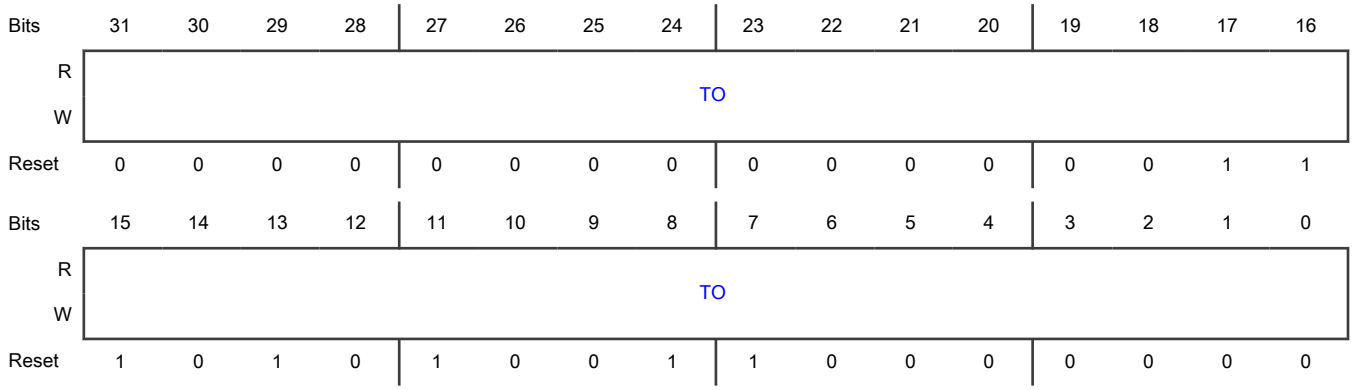
Offset

Register	Offset
NCF_TO	B4h

Function

See NCF_TO[TO]

Diagram



Fields

Field	Function
31-0 TO	Non-critical-Fault Alarm-State Timeout Interval Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Controls the maximum amount of time that FCCU can be in the ALARM state ($T_{Max\ Alarm}$) according to this equation: $T_{Max\ Alarm} = TO \times T_{CLKSAFE}$ where $T_{CLKSAFE}$ is the safe-clock period. If FCCU enters the ALARM state (because a fault occurs on an enabled non-critical fault channel for which the ALARM state is enabled) and this timeout interval expires (called an Alarm-state timeout), then FCCU leaves the ALARM state and enters the FAULT state. **NOTE** Make sure the Alarm-state timeout interval is less than the FOSU module's timeout interval; otherwise, a fault that occurs while FCCU is in the ALARM state can cause FOSU to generate a chip reset. The FOSU timeout interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

52.7.1.12 Configuration-State Timeout Interval (CFG_TO)

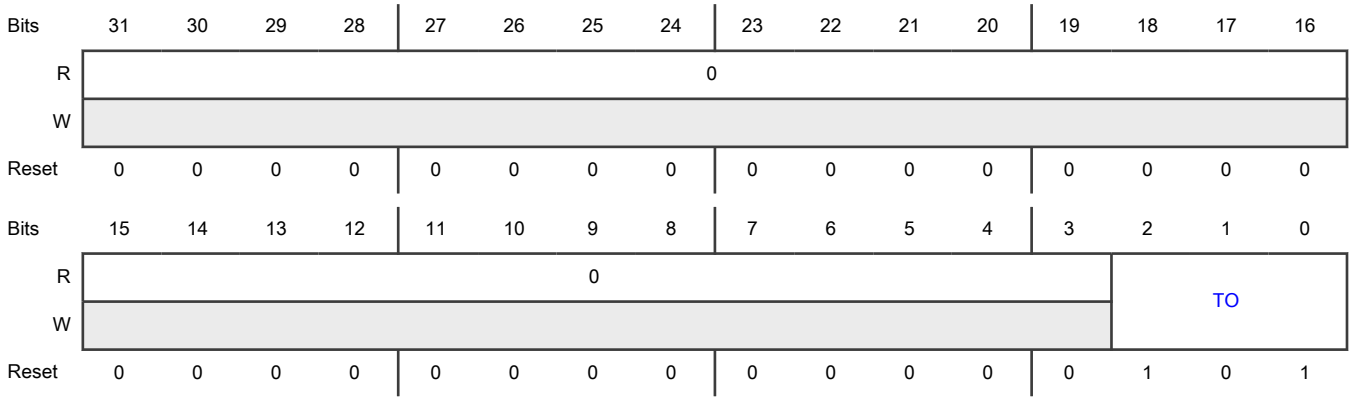
Offset

Register	Offset
CFG_TO	B8h

Function

See CFG_TO[TO]

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 TO	Configuration-State Timeout Interval Writable only when FCCU is in the NORMAL, ALARM, or FAULT state (not in the CONFIG state). Changed by FCCU to its reset value when a Configuration-state timeout occurs. Not accessible while a Configuration-state timeout (OP14 operation) is in progress. Controls the maximum amount of time that FCCU can be in the CONFIG state ($T_{\text{Max configuration}}$) according to this equation: $T_{\text{Max configuration}} = T_{\text{CLKSAFE}} \times 2^{(\text{TO} + 13)}$ where T_{CLKSAFE} is the safe-clock period. If you put FCCU in the CONFIG state and this timeout interval expires (called a Configuration-state timeout), then FCCU: • Automatically leaves the CONFIG state and enters the NORMAL state • Changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration (CFG) register's Configuration-state-timeout value, see CFG register bit value at different events. For a list of configuration registers, see Configuration registers.

52.7.1.13 IO Control (EINOUT)

Offset

Register	Offset
EINOUT	BCh

Function

The EINOUT register allows the following operations typically in the NORMAL state:

- To control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (CFG[FOM])

- To control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (CFG[FOM])
- to observe the state of signals at EIN[1:0] pins

The following table shows Bi-Stable encoding.

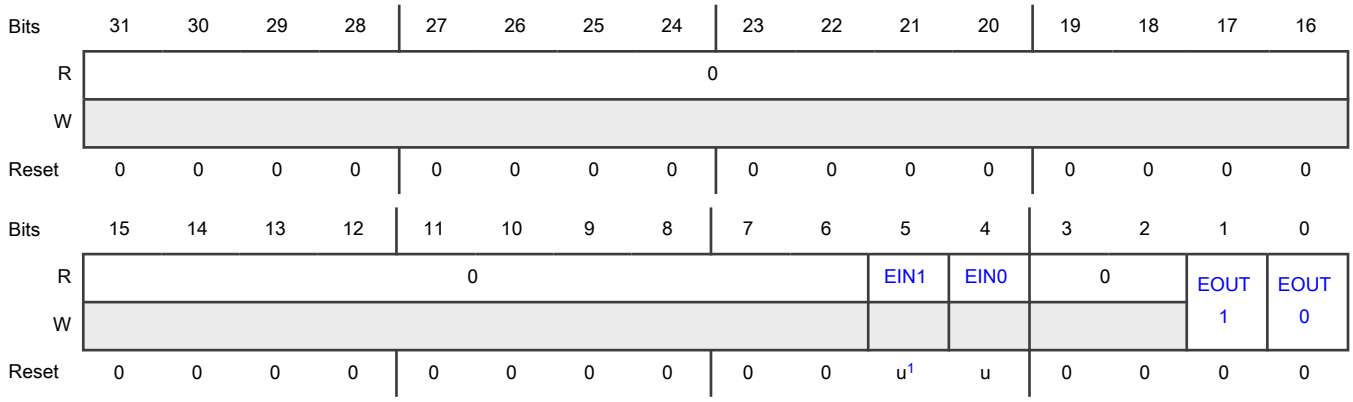
Table 297. Bi-Stable encoding

Mode = CFG[FOM]	EOUT[0]	EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

NOTE

Because of the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the EINOUT register.

Diagram



1. Reset value varies as per the corresponding EIN signal.

Fields

Field	Function
31-6 —	Reserved
5 EIN1	Error Input 1 Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN1 signal. 0b - Low 1b - High
4 EIN0	Error Input 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN0 signal. 0b - Low 1b - High
3-2 —	Reserved
1 EOUT1	EOUT1 Error out 1 (significant only if the CFG.FOM = Test1 or Test0 => EOUT[1] configured in output mode). The EOUT1 set/clear the respective EOUT[1] output signal if CFG.FOM = 110 or 101, otherwise it is a "don't-care" value. **NOTE** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0b - force EOUT[1] = 0 1b - force EOUT[1] = 1
0 EOUT0	EOUT0 Error out 0 (significant only if the CFG.FOM = Test1 or Test2 => EOUT[0] configured in output mode). The EOUT0 set/clear the respective EOUT[0] output signal if CFG.FOM = 110 or 111, otherwise it is a "don't care" value. **NOTE** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0b - force EOUT[0] = 0 1b - force EOUT[0] = 1

52.7.1.14 Status (STAT)

Offset

Register	Offset
STAT	C0h

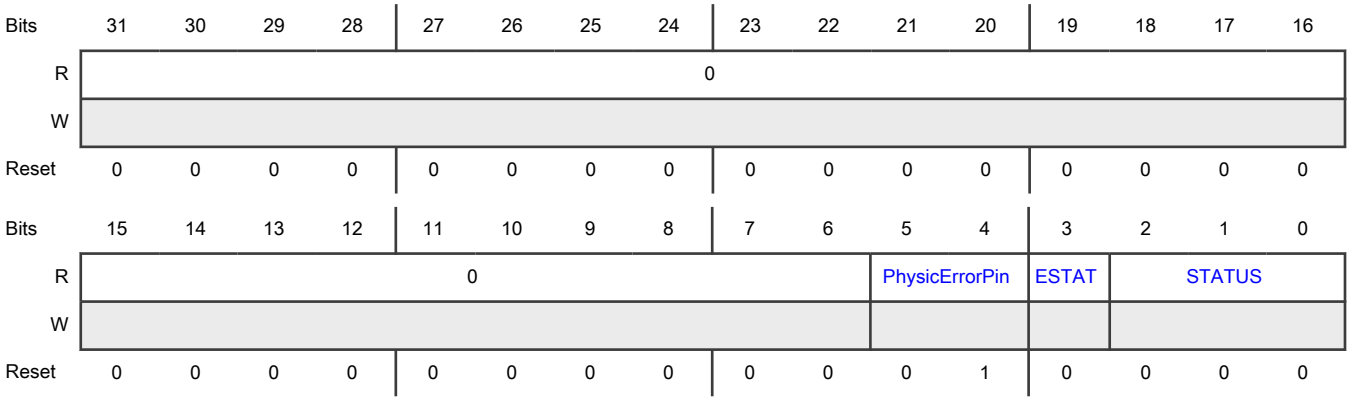
Function

This register indicates the following:

- States that FCCU is driving on the EOUT signals
- Whether FCCU is in a faulty condition

- Current state of FCCU

Diagram



Fields

Field	Function
31-6 —	Reserved
5-4 PhysicErrorPin	EOUT Signal States Applies only when the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]). Indicates the states that FCCU is driving on the EOUT signals. 00b - EOUT1 is low; EOUT0 is low. 01b - EOUT1 is low; EOUT0 is high. 10b - EOUT1 is high; EOUT0 is low. 11b - EOUT1 is high; EOUT0 is high.
3 ESTAT	FCCU Faulty Condition Indicates whether FCCU is in faulty condition (as indicated by the EOUT signals). For more information, see The FCCU conditions. 0b - Not in faulty condition (in non-faulty or configuration condition) 1b - In faulty condition

FFh: Multiple Fault-to-Alarm-state transitions

52.7.1.19 Non-critical Fault Fake (NCFF)

Offset

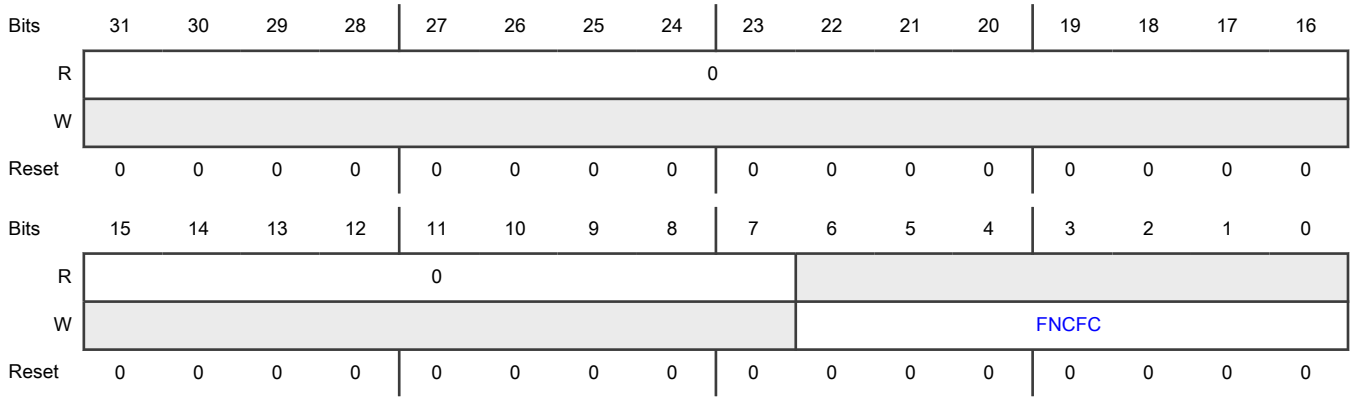
Register	Offset
NCFF	DCh

Function

This register contains a unique code to set a non-critical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the non-critical faults, by injecting the fault directly in the FAULT root, to verify the entire path and reaction. The reaction following a fake non-critical fault cannot be masked.

This is a write-only register with a set of codes corresponding to each non-critical fault injection.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-0 FNCFC	FNCFC Fake non-critical fault code **NOTE** Writing to this field injects fake faults; writing 00 and the default value being 0 renders different results. 00h: Fake non-critical fault injection at non-critical fault source 0 01h: Fake non-critical fault injection at non-critical fault source 1 02h: Fake non-critical fault injection at non-critical fault source 2 ... 7Fh: Fake non-critical fault injection at non-critical fault source 127

52.7.1.20 IRQ Status (IRQ_STAT)

Offset

Register	Offset
IRQ_STAT	E0h

Function

This register provides the FCCU interrupt status related to the following events:

- Configuration-state timeout error
- Alarm interrupt
- NMI interrupt

The configuration-state timeout interrupt is asserted if both IRQ_STAT[CFG_TO_STAT] and IRQ_EN[CFG_TO_IEN] bits are asserted. It is cleared when a 1 is written to the IRQ_STAT[CFG_TO_STAT] bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the IRQ_STAT trace the status of the related interrupt lines.

7-0 EOUTENn	Non-critical Fault-State EOUT Signaling Enable n Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Applies only when the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]). When FCCU is configured for Bi-Stable fault-output mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	(CFG[FOM]), controls whether EOUT signaling is enabled as a Fault-state reaction for the associated non-critical fault channel (n). (For other fault-output modes, EOUT signaling is always enabled, regardless of the value of this field.) When EOUT signaling is enabled for an enabled non-critical fault channel, a fault on that channel causes FCCU to indicate the faulty condition on the EOUT[1:0] signals when FCCU enters the FAULT state. For information on how to configure the non-critical fault channels, see Configure the non-critical fault channels. For all fault-output modes, also controls whether FCCU asserts the FIF signal when a fault on the associated non-critical fault channel (n) causes FCCU to enter the FAULT state. **NOTE** For all fault-output modes, you must set this field to enabled to ensure that FCCU asserts the FIF signal when FCCU enters FAULT state as the result of a fault on the associated non-critical fault channel (n) so the FOSU module does not mistakenly generate a destructive chip reset. 0b - In Bi-Stable fault-output mode, both EOUT signaling and FIF assertion are disabled; in other fault-output modes, EOUT signaling is enabled and FIF assertion is disabled. 1b - Both EOUT signaling and FIF assertion are enabled in all fault-output modes.

52.7.1.28 Alarm-State Timer (TMR_ALARM)

Offset

Register	Offset
TMR_ALARM	12Ch

Function

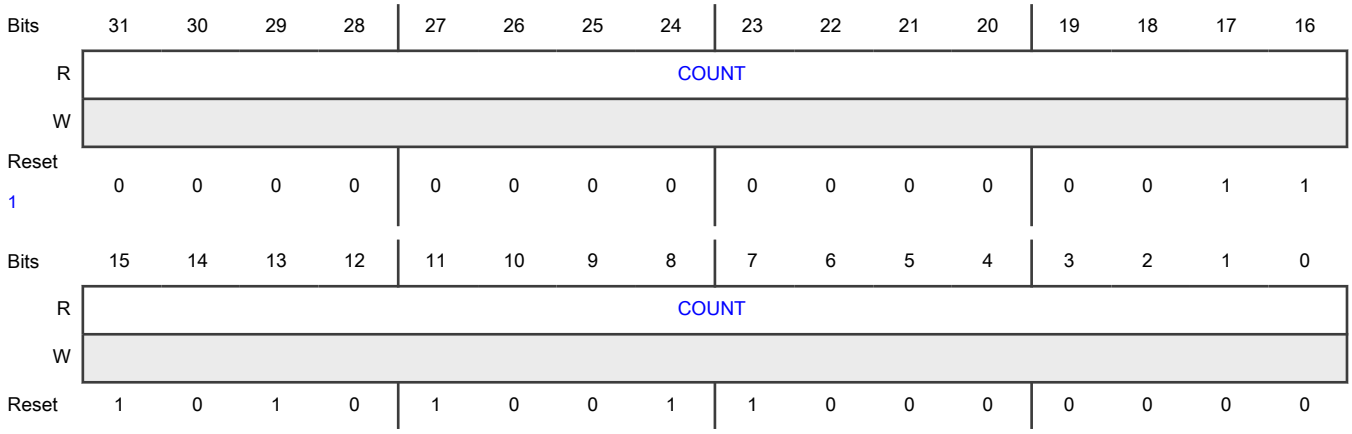
See TMR_ALARM[COUNT].

This table shows how the Alarm-state timer's state and value vary by FCCU state:

Table 298. TMR_ALARM reset value

FCCU state	Timer state	Timer value
CONFIG	Idle	0000_0000h
NORMAL	Idle	Initial value: NCF_TO[TO]
ALARM	Running	Value when read
FAULT	Idle	End of count

Diagram



1. The default reset value is provided by NCF_TO[TO]. See Table 298 for the reset value at different FCCU states.

Fields

Field	Function
31-0 COUNT	Alarm-State Timer Count Specifies the value of the Alarm-state timer in CLKSAFE periods.

52.7.1.29 Configuration-State Timer (TMR_CFG)

Offset

Register	Offset
TMR_CFG	134h

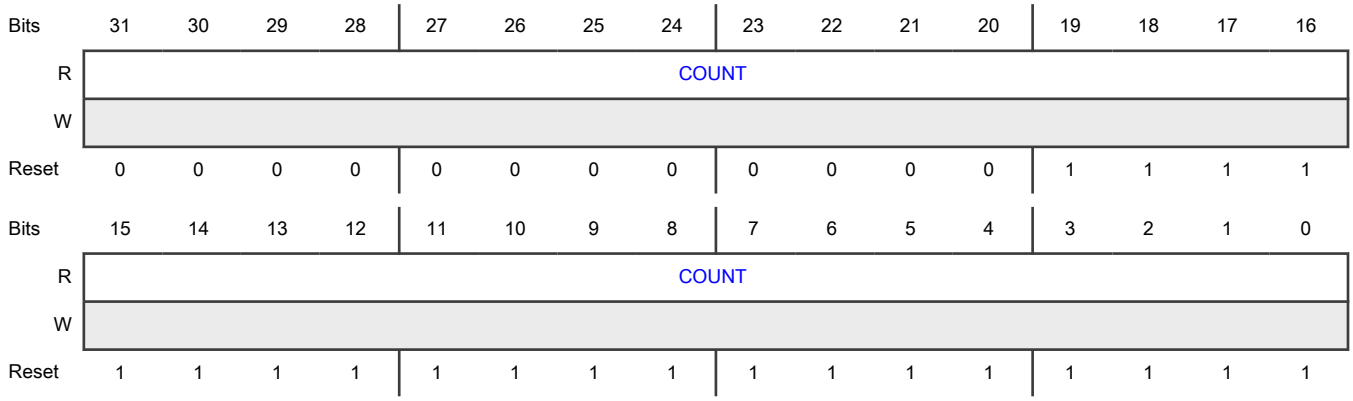
Function

See TMR_CFG[COUNT].

This table shows how the Configuration-state timer's state and value vary by FCCU state:

FCCU state	Timer state	Timer value
CONFIG	Running	Value when read
NORMAL	Idle	000F_FFFFh
ALARM	Idle	000F_FFFFh
FAULT	Idle	000F_FFFFh

Diagram



Fields

Field	Function
31-0 COUNT	Configuration-State Timer Count Specifies the value of the Configuration-state timer in CLKSAFE periods.

52.7.1.30 Fault-Output Timer (TMR_ETMR)

Offset

Register	Offset
TMR_ETMR	138h

Function

See TMR_ETMR[COUNT].

This table shows how the fault-output timer's state and value vary by FCCU state and fault-output mode:

FCCU state	Timer state (value)
CONFIG	Not Fault-Toggle: Idle (0000_0000h) Fault-Toggle: Running (value when read) or idle (0000_0000h)
NORMAL	Not Fault-Toggle: Idle (0000_0000h) Fault-Toggle: Running (value when read) or idle (0000_0000h)
ALARM	Not Fault-Toggle: Idle (0000_0000h) Fault-Toggle: Running (value when read) or idle (0000_0000h)

Table continues on the next page...

Table continued from the previous page...

FCCU state	Timer state (value)
FAULT	Not Fault-Toggle: Running (value when read. It is an up-counter which rollbacks to zero after reaching maximum value and then it begins counting again.) Fault-Toggle: Running (value when read) or idle (0000_0000h)

Fields

Field	Function
31-0 COUNT	Fault-Output Timer Count Specifies the value of the fault-output timer in CLKSAFE periods.

52.7.2 Configuration registers

52.7.2.1 Definition

Configuration registers are registers that:

- Let you configure FCCU's Alarm-state timer interval, fault channels, and fault-output (EOUT) signals.
- You can write to only when the configuration is not locked and FCCU is in CONFIG state (see Put FCCU in the CONFIG state).
- Save the values you write to them while FCCU is in CONFIG state only after you manually put FCCU in NORMAL state. If FCCU automatically leaves CONFIG state and enters NORMAL state because the configuration-timer interval (CFG_TO[TO]) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value; FCCU also changes the value of the Configuration-State Timeout Interval (CFG_TO) register to its reset value. For information on the Configuration-state timeout value, see CFG register bit value at different events.

52.7.2.2 Configuration registers

Following is the list of configuration registers in this module. They are listed in an offset order from lowest to highest.

- Configuration (CFG)
- Non-critical Fault Configuration (NCF_CFGa)

- Non-critical Fault-State Configuration (NCFS_CFG0)
- Non-critical Fault Enable (NCF_E0)
- Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)
- Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)
- Delta T (DELTA_T)
- Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0)
- Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)
- Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)

52.7.3 CFG register bit value at different events

In this chip, there are no events that affect the bits in the configuration register.

52.8 Glossary

CF	Critical fault
EOUT	Error out
FOSU	FCCU output supervision unit
FSM	Finite state machine
intf	Interface
IRQ	Interrupt request
NCF	Non-critical fault
NMI	Non-maskable interrupt

Chapter 53
Self-test General-Purpose Registers (SELFTEST_GPR)

53.1 Introduction

SELFTEST_GPR configures the STCU2 LBIST shift cycles. Programming self-test GPRs is a part of the self-test programming sequence. See the "Self-test programming sequence" section in the STCU2 chapter.

NXP supports only STCU2 Built-In Self-Test (BIST) sequences that have been validated by NXP for in-field testing usage.

The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative).

The values for SELFTEST_GPR registers must be aligned with the NXP supported configurations only.

NOTE

SELFTEST_GPR is not present in S32K312 and S32K311.

NOTE

While accessing SELFTEST_GPR space, software must ensure that the STCU2 block has its clock enabled, i.e., MC_ME.PRTN1_COFB3_CLKEN[REQ104] configured as 1'b1. Not ensuring this might result in unpredictable device behaviour.

53.2 Peripheral shift clock switching (PCS)

The PCS feature is used to avoid current surges at the start and/or end of LBIST. Since LBIST can cause sudden current surges which might lead to chip malfunction.

With PCS enabled, there are additional (SELFTEST_GPR.CONFIG_GPR[PCS_STEP_SIZE] + 1)*16 patterns beyond the configured count. If enabled at the start of LBIST (using SELFTEST_GPR.CONFIG_GPR[PCS_ENABLE_START]), it would cause the shift clock to scale up in this duration from divide by 16 to the original frequency (by changing divider in each step).

Similarly, if configured at the end of LBIST (using SELFTEST_GPR.CONFIG_GPR[PCS_ENABLE_END]), the shift clock frequency will be scaled down from original frequency to divide by 16.

53.3 SELFTEST_GPR register descriptions

53.3.1 SELFTEST_GPR memory map

SELFTEST_GPR base address: 403B_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Configuration register (CONFIG_REG)	32	RW	0000_ADD5h
14h	LBIST Program (LBIST_PROG_REG)	32	RW	0003_0050h

53.3.2 Configuration register (CONFIG_REG)

Offset

Register	Offset
CONFIG_REG	0h

53.3.3 LBIST Program (LBIST_PROG_REG)

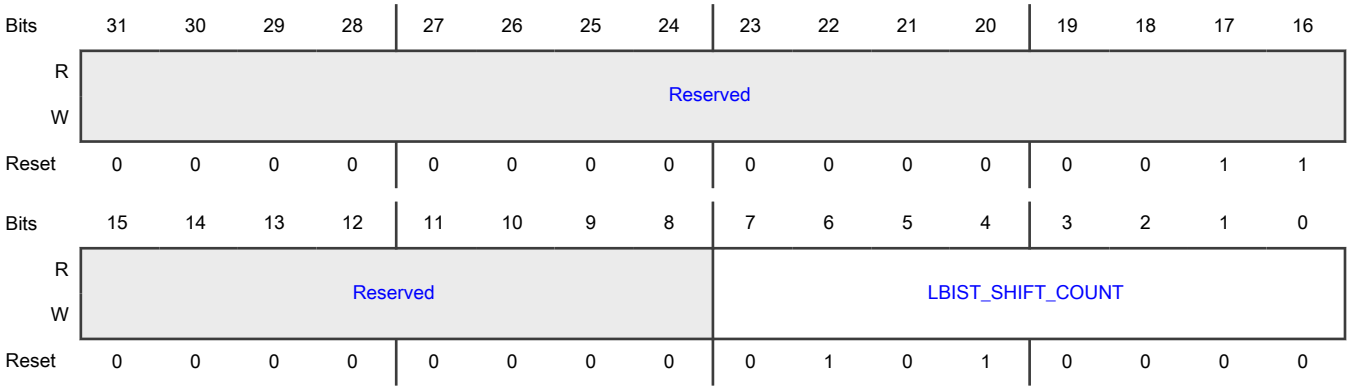
Offset

Register	Offset
LBIST_PROG_REG	14h

Function

Configures the LBIST shift count.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 LBIST_SHIFT_COUNT	LBIST Shift Count Specifies the number of shift cycles in a scan chain in one pattern count for the LBIST partition.

53.4 Glossary

BIST clock	The BIST clock refers to the BIST operational clock which is the clock source used while LBIST is operational by the LBIST controller, which is the MC_CGM clock node LBIST_CLK for the chip. See the system block diagram for details.
LBIST	Logic built-in self-test
Pattern count	The pattern count refers to an empirically determined value of shift patterns run in LBIST on a scan chain to result in predetermined fault coverage, based on device safety integrity level. Since the LBIST scheme is Pseudo Random Testing, a sufficiently good value of pattern count is used which provides the required fault coverage.
Scan chain	A sequential chain of flops in scan mode over which one scan pattern (generated by PRPG, that is, Pseudo Random Pattern Generator) in LBIST will be shifted and the output MISR (Multi Input Signature Register) will be matched with earlier known value to determine pass or fail criterion of that particular chain.

Chapter 54
Self-Test Control Unit (STCU2)

54.1 Chip-specific STCU2 information

54.1.1 Supported BIST sequences

This chip supports only STCU2 BIST sequences that NXP has validated for in-field testing usage. The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative for this information).

54.1.2 Self-test overview

STCU2 provides the overall control of both LBIST and MBIST, in serial or parallel, depending on the power, timing, or coverage constraints.

NOTE

LBIST is not available for S32K312, S32K311, and S32K310.

The application software initiates the self-test sequence or procedure (please use whichever term is correct), and has provisions to bypass the self-test configuration to directly move to normal Run mode.

There is a programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence. In case the selected LBISTs or MBISTs are not complete during the assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into ERR_STAT[WDTOSW] and MBESWx or LBESW.

The STCU2 execution includes three phases:

- Software configuration. Load or program the test configuration parameters to be executed, depending on ASIL target and performance requirements. The self-test configuration parameters allow the self-test sequence to run with different times depending on pattern numbers and types, achieving different levels of coverage.
- Start of BIST execution. This involves software register configuration in STCU2. The BIST completion is followed by a functional reset.
- End of BIST execution. After BIST execution and functional reset are complete, the BIST results are made available and you decide how to continue (trigger a new reset or start a safety application). The BIST execution completion is signalized in an internal STCU2 register (LBESWn) bit which is not affected by the functional reset. The BIST test results are also not affected by the functional reset.

The following figure shows a pictorial representation of two LBIST partitions having two and one MBIST groups, respectively. STCU2 interacts with LBIST_CTRL for the respective partitions to configure and control the LBIST sequence and compare results. It also interacts with MTR controller (MCT) for MBIST. Each LBIST partition has its corresponding controller whereas a single MCT can cater to multiple MBIST groups.

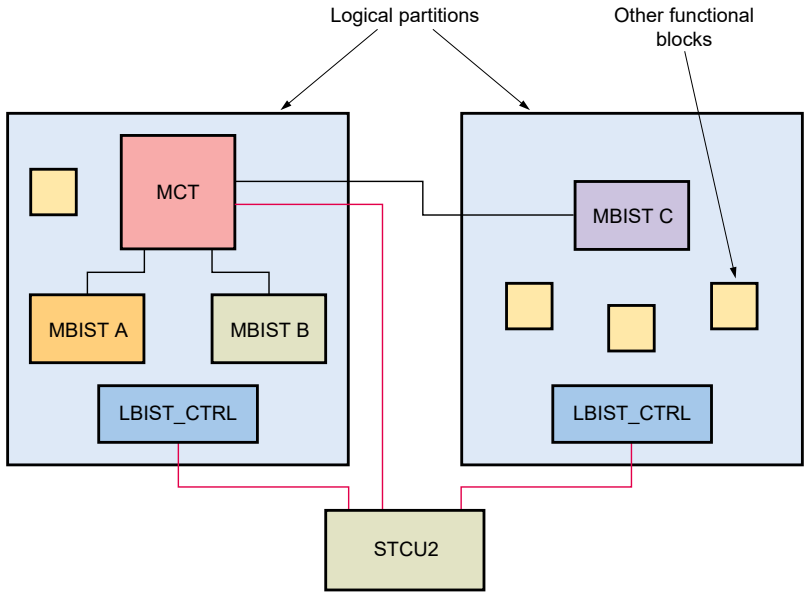


Figure 215. Self-test overview

NOTE

LBIST_CTRL is not available for S32K312, S232K311, and S32K310.

Each LBIST partition also includes a block called Self-test GPR involving a set of registers that provide miscellaneous configuration and parameter details for an LBIST operation.

When you trigger a self-test sequence, the chip becomes unavailable for software application during the self-test run.

54.1.3 STCU2 LBIST/MBIST mapping

This topic covers STCU2 LBIST/MBIST mapping.

LBIST mapping

The below table lists the LBIST mapping of the chip. The NLBIST value is 1.

Table 299. LBIST mapping

BIST ID (NLBIST)	BIST instance name	Modules

54.1.4 Clock connectivity

STCU2 works on the system clock domain. The scan operations while LBIST are done on TCK clock.

Table 308. Clock connectivity

STCU2 clock	Clock connected to the chip	Remarks
STCU2 CORE_CLK	AIPS_SLOW_CLK	System clock divider output clock node for STCU2 operations and register interface accesses
REG_INTF_CLK		
SHIFT_CLK	JTAG_TCK	JTAG_TCK used for shift operations when self-test is in progress

54.1.5 Memory map for self-test GPRs

See the memory map file attached to this document and 'SELFTEST_GPR' chapter for details.

54.1.6 Handling unrecoverable faults

Only recoverable and non-critical faults from STCU2 are mapped to FCCU. The unrecoverable and critical faults are mapped to MC_RGM. Therefore, ignore any references to mapping of unrecoverable and critical faults with FCCU in this chapter.

54.1.7 Indicating fault state during the main reset domain Self-Test

FCCU EOUT indicates the fault state during the Self-Test as soon as the UTEST_MISC[FCCU_EOUT_ DEDICATED] is enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is enabled at the time of Self-Test setup steps.

The fault state remains asserted until the bit DCMRWD2[EOUT_STAT_DUR_STEST] is cleared post Self-Test reset sequence.

In case it is not required to indicate the fault state during the Self-Test, then the bit DCMRWD2[EOUT_STAT_DUR_STEST] should not be programmed.

54.1.8 Error events management in main reset domain Self-Test

Error events should be mapped to unrecoverable faults in STCU2_ERR_FM register for main reset domain Self-Test.

54.1.9 AUTOLOCK_VALUE for register write access via STCU2_SKC

Register write-access watchdog timer explains that access to STCU2 registers via the STCU2_SKC security-key mechanism times out after a number of STCU2 clock cycles equal to AUTOLOCK_VALUE. On this chip, AUTOLOCK_VALUE is 32'hFFFF_FFFF.

54.1.10 PLL loss of lock during Self-Test

Detection of PLL loss of lock during LBIST or MBIST causes a destructive reset in the system.

CMU0 programming is required before the Self-Test programming begins.

All the registers present in LBIST domains do not retain their content after Self-Test reset.

54.1.11 STCU2 BIST start (BSTART) register description

Attempted accesses with the undefined reserved values in the BSTART register can result in undefined behavior. The following table defines the BSTART field on this chip.

Table 309. BSTART description

Field value	Description
000b	NOP (reset value)
001b	RUN_ONLY: Run BISTs. MTR controller (MCT) runs the selected BISTs without programming them first.
010b	Reserved
011b	Reserved
100b	PROG_ONLY: Program BISTs only. MCT only programs BISTs and does not start them. This enables different BISTs to be programmed with different algorithms before all the selected BISTs are started using the RUN_ONLY command.
101b	PROG_RUN: Program BISTs and start them.
110b	Reserved
111b	Reserved

Table 310. STCU2 BIST start (BSTART) field description

Field	Description
31 CLKEN	IPS clock enable, enables the IPS clock for BIST's. 0b - If cleared, disables the clock 1b - Enables the IPS clock for BIST's

54.1.12 STCU2 algorithm select (ALGOSEL) register description

This register selects any one of the predefined algorithms. The value used in this register is mapped to a predefined algorithm register in BIST. After MCT has programmed information on this register and starts some BIST operation, this value is transferred to the predefined algorithm register in every BIST that is selected.

If multiple predefined algorithms are selected, the order of execution is from LSB to MSB.

Any field that does not have a predefined algorithm associated with it is a reserved bit. No data is written to reserved bits and when you read these bits, they always return 0. These predefined algorithms include:

- Backgrounds
- Address modes and other register programming that may be necessary
- The number of BIST runs needed to perform the exact coverage requested.

MCT decodes this information through a series of look-up tables. The following table describes the high-level BIST algorithms that can be invoked through the MCT. The columns in that table have the following meaning:

- Index: The position in this MCT register enables this algorithm.
- Name: The symbolic name for this algorithm.
- Description: The intent and use model for this algorithm.
- BIST runs: The sequence of BIST invocations comprising this algorithm.
- Sequences: The ordered list of march elements to run. Each march element consists of a direction indicator (for increasing addresses and for decreasing addresses) and a set of march phases. A march phase consists of reading (R) or writing (W), the non-inverted (0) or inverted (1) background pattern.
- Used by default: Whether this algorithm is selected in the post-reset state of this register.

Table 311. ALGOSEL description

Index	Name	Description	BIST runs	Sequences	Used by default
3	March C+ single	March C+ with column fast and solid background	MarchC+ column fast 1x (#4)	W0, R0W1, R1W0R0W1, R1W0, R0W1R1W0, R0	Yes
13	BasicChk	Basic selfcontained checkerboard, using column fast	BasicChk (#18)	R0W1R1	-

54.1.13 Self-Test programming sequence

This section describes a high level programming sequence for executing Self-Test. The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative).

- Program clock sources and MC_CGMs as per the clock configuration.

  NOTE

  While running MBIST on EMAC timestamp memory, MC_CGM.MUX_9_DC_0[DIV] should be appropriately configured to ensure EMAC_CLK_TS should be atleast 1.5 times the AIPS_SLOW_CLK frequency.

- Program SELFTEST_GPR[CONFIG_REG] and SELFTEST_GPR[LBIST_PROG_REG] as per the LBIST configurations.

  NOTE

  This is not applicable for S32K312 and S32K311 wherein LBIST is not supported.

- Program STCU2 as per NXP recommended.

- Program dcf_client_utest_misc[FCCU_EOUT_DEDICATED] and DCMRWD2[EOUT_STAT_DUR_STEST] to configure EOUT pins as dedicated and to indicate FCCU error states on EOUT pins during Self-Test respectively.
- Configure ERCTRL[ERASSERT] register bit in MC_RGM to achieve desired behaviour of Reset Pin as documented in Reset Section and Pad States Section.
- Disable functional reset sources to avoid false Self-Test abort scenarios. For example, software watchdog timers cannot be serviced while Self-Test because the software is not accessible and can cause invalid timeout reset. See Reset events and configurations while Self-Test.
- Program the PCS_ENABLE[8:7] fields of the CONFIG_REG register (SELFTEST_GPR) to 0 to disable PCS.
- Trigger Self-Test execution by programming RUNSW register in STCU2.
- At the end of the Self-Test run, a functional reset is generated. Out of reset, the software can check the status registers inside STCU2 and take actions accordingly.

NOTE

EIM should be disabled when STCU based Self-Test is running.

54.1.14 Modules operation during/post Self-Test

The clock, reset, power generation modules, such as RGM, PMC, CGM, FIRC, PLL, and SIRC will be available during and post Self-Test. However, because the chip undergoes the reset sequence, PLL and CGM will be reset.

CMU0 and CMU3 will be available during Self-Test if enabled prior to Self-Test, but will be Reset post Self-Test.

STCU2 will also be available during Self-Test and the results can be read post Self-Test.

54.1.15 Reset events and configurations while Self-Test

As Self-Test is a software initiated Self-Test, it is expected by software to ensure all the peripherals are disabled as documented in Software considerations before Self-Test.

The functional reset sources should be appropriately configured to avoid any functional reset while Self-Test is running (disable SWT_RST and HSE_SWT_RST. JTAGC should not be in EXTEST, HIGHZ or CLAMP instructions). This ensures no selftest abort while running selftest due to functional reset source. The below table specifies the state of functional reset sources for Self-Test.

Table 312. Reset events and configurations while self-test

Reset source	Reset description	Configurations/remarks for selftest
FCCU_RST	FCCU reset reaction	The FCCU is a part of logic which is under Self-Test and thus it would be disabled during the Self-Test
ST_DONE	Self-Test done reset	The selftest done indication resets the device post selftest. While Self-Test is running, the Self-Test done indication will be in disabled state
SWT_RST	SWT reset request	SWT should be disabled in Self-Test configuration sequence.
JTAG_RST	JTAG Reset	JTAG communication should be inactive while Self-Test and JTAGC state machine should not be in EXTEST, HIGHZ or CLAMP instructions
HSE_SWT_RST	HSE SWT timeout	HSE_SWT should be disabled in Self-Test configuration sequence.
SW_FUNC	software 'functional' reset	The software is inactive during Self-Test and hence software functional reset will not arrive while the chip is under Self-Test.
DEBUG_FUNC	debug 'functional' reset	MDM DAP should not be configured for debug functional reset generation while Self-Test is running.

The destructive reset sources are available while in Self-Test. In case of any destructive reset event, the device undergoes a destructive reset sequence, thereby resetting the STCU2 and Self-Test logic itself.

After completion of Self-Test (LBIST or MBIST), a functional reset sequence is executed by MC_RGM.

54.1.16 Software considerations before Self-Test

1. As all the communication peripherals are not in LBIST partitions; hence, it is required by SW to stop all communications and disable all the PCTLs of the communication peripherals before initiating Self-Test as the device will be unusable in Self-Test. This is needed so that there is graceful safe stating of inputs of non-lbisted peripheral modules.
2. Configure RGM functional reset sources as interrupts before Self-Test as per the considerations mentioned in Reset events and configurations while Self-Test, i.e., the SWTs should be disabled, the JTAGC should not be in states which can cause a JTAG reset event (EXTEST, HIGHZ, CLAMP instructions) and the software should not trigger a functional reset event via MC_ME or MDM_AP while the selftest is ongoing. This is to avoid any abort scenario due to any functional reset source as Self-Test is initiated by SW.

There is no issue with Reset pin as Reset pin is a source of destructive reset and will reset STCU2 and Self-Test related logic etc.

54.1.17 End of Self-Test

The Self-Test completion is a source of functional reset to the device, by which the device executes a functional reset sequence. The logic which is LBISTed additionally undergoes a complete POR sequence to ensure that the random content shifted during BIST sequence get cleared.

At the end of MBIST, the software should execute below steps:

1. Software reads the MBIST end flag to identify that the MBIST sequence had ended properly without any interruption or abort, by reading STCU2.MBESWn.
2. Software reads the MBIST status to identify whether the MBIST was successful or not, by reading STCU2.MBSSWn.

NOTE

The MBIST status should always be read in accordance with MBIST end flag. The STCU2.MBSSWn status is irrelevant if STCU2.MBESWn indicates that MBIST execution is incomplete.

At the end of LBIST, the software should execute below steps:

1. Software reads the LBIST end flag to identify that the LBIST sequence had ended properly without any interruption or abort, by reading STCU2.LBESWn.
2. Software reads the LBIST status to identify whether the LBIST was successful or not, by reading STCU2.LBSSWn.

NOTE

The LBIST status should always be read in accordance with LBIST end flag. The STCU2.LBSSWn status is irrelevant if STCU2.LBESWn indicates that LBIST execution is incomplete.

54.2 Introduction

STCU2 is a comprehensive programmable hardware module that:

- Manages the execution of BISTs
- Indicates whether each BIST passed
- Manages the chip's LBIST and the MBIST blocks

54.3 Main features

STCU2 includes:

- System interface for reading from and writing to the STCU2 registers (online) via the CPU

- Programmable scheduler for BIST execution
- Control over LBIST concurrent or sequential execution
- Control over MBIST concurrent or sequential execution
- Programmable LBIST delayed concurrent start
- Programmable internal clock prescaler to reduce internal and BIST clocks
- PLL lock signal monitoring during BIST sequences
- Programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence
- Fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
- Fields that indicate the pass/fail indication of each BIST, see Types of BIST sequences and Types of BIST partitions
- Fields that indicate the status of each type of online STCU2 internal error condition
- Programmable fault mapping of each BIST for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the BIST fails to execute
- Programmable fault mapping of each STCU2 internal error condition for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the condition occurs
- Signals to report recoverable and unrecoverable faults to the FCCU module
- Redundant recoverable and unrecoverable fault-generation logic to improve reliability
- FCCU recoverable and unrecoverable fault-injection mechanism
- Global register write-protection mechanism that requires two security key codes
- Global automatic power saving after a BIST sequence is completed when watchdog timer time-out is detected
- Watchdog automatic clock wake-up mechanism when software unlocks the STCU2 registers for write access
- Watchdog automatic power saving when the fixed register-write-access watchdog timer times out

54.4 Block diagram

This diagram shows the parts of STCU2:

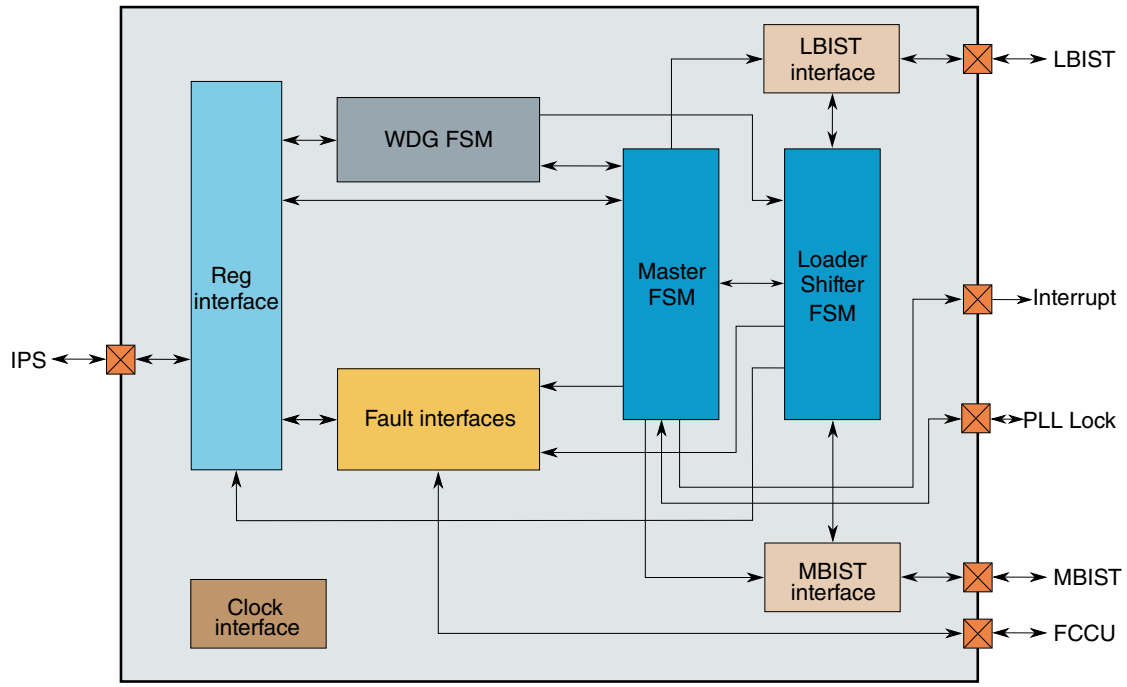

Figure 216. STCU2 block diagram

This table describes the parts of STCU2:

Table 313. STCU2 parts

Part	Function
Reg interface	Provides access to: • Registers • The security key logic • The IPS interface
Fault interfaces	Performs the following tasks: • Collects the fault conditions caused by STCU2 internal error conditions and each BIST executed in a sequence • Sets the global recoverable or unrecoverable status flag, depending on the fault mapping for a given BIST • Manages the recoverable and unrecoverable fault lines to and from the FCCU module • Manages the set/clear injection mechanism provided by the FCCU module To improve the intrinsic reliability of this critical logic, the generation logic is duplicated.
Clock interface	Manages the internal and the BIST clock prescaler, the internal clock-gating power saving, and the wake-up clock feature

Table continues on the next page...

Table 313. STCU2 parts (continued)

Part	Function
WDG FSM	Provides the following: • A programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence • A fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
Master FSM	Coordinates and schedules all of the operations performed during a BIST sequence
Loader Shifter FSM	Programs the BIST registers and reads back the data to be checked at the end of each test operation
LBIST interface	Provides the interface between the chip's LBIST engines and the STCU2 controllers
MBIST interface	Provides the interface between the MBIST controller and the STCU2 controller

54.5 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration purposes via CPU. The module supports the following bus read operations:

- Word (32 bits) data read operations to any registers
- Any other operation is not supported.

Word, low and high half-words, byte operations are supported in write mode only:

- Write access is allowed by software only when CFG[WRP] is cleared. The default value of CFG[WRP] is cleared, exceptions are the following read/write fields: CFG[WRP], ERR_STAT[UFSF] and ERR_STAT[RFSF].
- STCU2 Configuration (CFG) should only be accessed in 32 bit (partial access not allowed).

The STCU2 module generates a transfer error in the following cases:

- Any read access to the registers after writing Key1 and before writing Key2 (in online) and before register write-access watchdog timer expires.
- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied
- Any write operation performed on registers when CFG[WRP] is set and the access is performed through software (internal peripheral interface). The exceptions are SKC register (for valid keys value and sequence) in which STCU2 does not assert transfer error.
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor, or test.

In case there are write operations on bits marked as reserved, the transfer error is not generated.

NOTE

See the chip-specific STCU2 information for the wait time necessary to write to the online registers.

54.6 BISTs and BIST partitions

54.6.1 Definition: BIST

A BIST is a test that the chip can execute to verify the functional integrity of a part of itself. The chip uses STCU2 and other on-chip hardware to execute a BIST.

54.6.2 Definition: BIST partition

A BIST partition is a part of a chip for which a BIST has been defined. The hardware that is included in a given BIST partition is chip-specific. For a list of the hardware included in each of the BIST partitions on this chip, see the chip-specific STCU2 information.

54.6.3 Example: BIST partitions on a chip

This is an example of a chip with six BIST partitions:

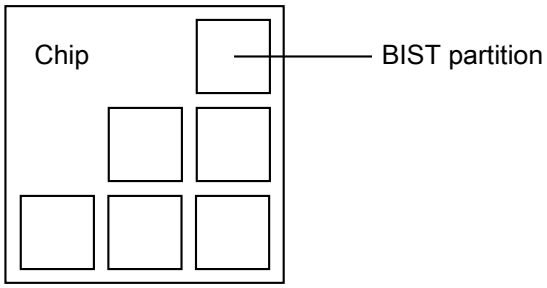

Figure 217. BIST partitions on a chip

54.6.4 Types of BIST partitions

The STCU2 module on this chip supports the following types of BIST partitions:

Table 314. Types of BIST partitions

BIST partition type	Description
MBIST partition	An SRAM or ROM block
LBIST partition	One or more digital modules

54.7 BIST sequences

54.7.1 Definition: BIST sequence

A BIST sequence is a programmable series of one or more phases, each of which executes one or more individual BISTs.

54.7.2 STCU2 executes MBISTs before LBISTs

If a BIST sequence includes both MBISTs and LBISTs; STCU2 executes the MBISTs first.

54.7.3 Example: Single-phase BIST sequence

This is an example of a single-phase BIST sequence in which STCU2 executes only one BIST:

Table 315. Example: Single-phase BIST sequence

Phase	BIST executed
0	MBIST 16

54.7.4 Example: Multi-phase BIST sequence

This is an example of a multiphase BIST sequence in which STCU2 executes more than one BIST in parallel in some phases:

Table 316. Example: Multi-phase BIST sequence

Phase	BISTs executed
0	MBISTs 7, 30
1	MBIST 23
2	MBISTs 6, 16, 29, 23
3	LBIST 12
4	LBISTs 13, 8, 11
5	LBISTs 19, 6

54.7.5 Types of BIST sequences

The STCU2 module on this chip supports these types of BIST sequences:

Table 317. Example: Types of BIST sequences

BIST sequence type	Description
Online BIST sequence	A BIST sequence that STCU2 executes during runtime at the request of software. Application software configures and initiates execution of the BIST sequence by loading values into STCU2 registers.

54.7.6 Supported BIST sequences

NXP supports only a specific set of BIST sequences for this chip. For the list of supported BIST sequences, see the chip-specific STCU2 information.

54.8 Functional description

54.8.1 FSM description

The module has three FSM that work together: Master FSM, Loader/Shifter FSM, and the Watchdog FSM. Basically the Master FSM is the core unit of the STCU2 module. It coordinates all the self-test operations and the other FSM. The Loader/Shifter FSM is used to program the MBIST and the LBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master FSM. The Watchdog FSM evaluates all the schedule time for MBIST and LBIST and the time-out in case of wrong STCU2 programming.

54.8.2 BIST scheduling

STCU2 is designed to program the parallel/serial execution of the MBIST or LBIST depending on the power, timing, and coverage constraints.

The mechanism used to provide this flexibility is a linked list of BIST descriptors where the starting pointer is defined in CFG[PTR]. The first LBIST is mapped on 0, the second on 1, and so on. A BIST descriptor identifies a LBIST or MBIST via an index that is associated with its control register (STCU2 LBIST Control (LB_CTRL0) or STCU2 MBIST Control (MB_CTRL0 - MB_CTRL18)). The first MBIST is mapped on (00000080h + 0), the second on (00000080h + 1), and so on. The additional pointers of the linked list are in LB_CTRL*n*[PTR] for LBIST *n* (where *n* is the selected LBIST) and MB_CTRL*m*[PTR] for MBIST *m* (where *m* is the selected MBIST) and must be populated depending on the selected run sequence. The additional fields LB_CTRL[CSM] and MB_CTRL[CSM] provide the flexibility to run concurrently or sequentially the chosen set of the LBIST or MBIST or to close the linked list by setting the NIL pointer.

54.8.3 FCCU interface

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable fault and/or a Recoverable fault failure during the Self Test sequence. Two independent signals have been used to mitigate the common cause faults.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

54.8.4 Watchdogs

The STCU2 implements different watchdogs to ensure that operations are finished in time.

54.8.4.1 BIST watchdog timer

The LBIST and MBIST execution time has to be configured as described in STCU2 Watchdog Granularity (WDG), to account for the overall execution time of the self test sequence. In case the selected LBISTs or MBISTs are not yet completed during assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into ERR_STAT[WDTOSW] and MBESWx or LBESW.

In case of multiple sequential run in the same online session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

54.8.4.2 Register write-access watchdog timer

As explained in the STCU2 SK Code (SKC):

- A key mechanism protects STCU2 registers during the self-test configuration phase by preventing any unwanted access.
- A hardware watchdog timer locks register-write access after a number of STCU2 clock cycles. To refresh the hardware watchdog timer before it times out, write Key1 and Key2 sequences.

AUTOLOCK_VALUE is the number of STCU2 clock cycles after which the hardware watchdog timer locks register-write access. See the chip-specific STCU2 information for the value of AUTOLOCK_VALUE.

The hardware watchdog timer is particularly useful in case CFG[WRP] is 0 during the software self-test configuration. In this case, the software application might enable write access to the STCU2 registers.

54.9 STCU2 register descriptions

The STCU2 registers are listed in this section.

NOTE

Always write the reset value for the Reserved fields.

During online self-test, after the STCU2 registers are configured, they must not be overridden via internal peripheral system until the self-test is complete.

54.9.1 STCU2 memory map

STCU base address: 403A_0000h

Offset	Register	Width (In bits)	Access	Reset value

54.9.3 STCU2 SK Code (SKC)

Offset

Register	Offset
SKC	8h

Function

The SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers.

To unlock STCU2 access after the STCU2 asynchronous reset and at the end of the STCU2 run, the software (IPS bus) need to apply the following sequence:

- write the key1 into the SKC register
- write the key2 into the SKC register

Depending on the online test step, the two keys are different. Byte write operation is not allowed because the full key has to be recognized as one unit.

A hard-coded WDG counter (Register write-access watchdog timer) starts decrementing its value right after POR is deasserted. Therefore, user must ensure to complete unlocking and programming sequence before its expiry. In case the STCU2 register access lasts more cycles than the one defined in the hard-coded WDG timeout, the STCU2 write access is locked and the WDG and register interface clocks are switched off. Also, in this case, to enable the write access to the STCU2 again and the WDG and register interface clocks, it is required to apply the sequence again. In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS is asserted. The STCU2 write access is locked and to unlock the access, the sequence has to be applied again. This can also happen if watchdog expires between key1 and key2. In this case, user needs to apply the key1-key2 sequence again. In case it is required to extend the STCU2 register access cycles before the hard-coded WDG timeout expires, Key1 and Key2 sequences need to be applied. The effect of this write operation is to re-initialize the WDG timeout counter. The STCU2 write access is locked and to unlock the access, the sequence has to be applied again.

The SKC register is not readable. The value 00000000h is always returned in case of read operation.

54.9.4 STCU2 Configuration (CFG)

Offset

Register	Offset
CFG	Ch

Function

The CFG register includes the global configuration of the STCU2 and can be updated in the online test steps.

The access to this register is described in the following figure. It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the online self-test case without restrictions.
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

Diagram

The punch-out mechanism is used to generate the derived clocks. The following configurations are allowed: 000b - sys_clk/1 001b - sys_clk/2 010b - sys_clk/3 011b - sys_clk/4 100b - sys_clk/5 101b - sys_clk/6 110b - sys_clk/7 111b - sys_clk/8

54.9.5 STCU2 Watchdog Granularity (WDG)

Offset

Register	Offset
WDG	14h

Function

The WDG register defines the time budget of LBIST and MBIST execution providing a protection mechanism in case of dead-lock or endless conditions during the self-test procedure.

In case online self-test sequence is run, it defines the timeout of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when online self-test phase is active and CFG[WRP] = 0.

54.9.6 STCU2 Error (ERR_STAT)

Offset

Register	Offset
ERR_STAT	24h

Function

The ERR_STAT register includes the status flags related to the STCU2 internal error conditions occurred during the configuration or the online self-testing execution.

The UFSF and RFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the following figure and as follows:

- If you select the byte write capability to write only UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

RF	Recoverable faults
UF	Unrecoverable faults

WDG FSM	Watchdog finite state machine

Chapter 55
Register Protection (REG_PROT)

55.1 Chip-specific REG_PROT information

55.1.1 REG_PROT configuration

The MCU safety relevant configuration registers are protected against unauthorized HW/S changes during read/write/clear access by implementing them with register protection module. See the REG_PROT details file attached to this document.

55.1.1.1 CMU_BRIDGE register protection

The CMUs in the device reside on a common peripheral slot as CMU_BRIDGE in the system memory map. Figure 218 indicates the locations of the CMUs alongwith the memory map.

Based on the CMU location in system peripheral memory map, the below locations in the CMU 16KB space are reserved and any access on these locations results in a bus transfer error.

402B_C018 – 402B_C01F

402B_C030 – 402B_C03F

402B_C050 – 402B_C05F

402B_C078 – 402B_C07F

402B_C098 – 402B_C09F

402B_C0B8 – 402B_C0BF

402B_C0D8 - 402B_CFFF

Since the register protection is available in the device for CMU_BRIDGE, the 4KB offset locations (refers as the Area 2 in register protection) are also reserved and accesses over these regions also result in bus transfer error.

402B_D018 – 402B_D01F

402B_D030 – 402B_D03F

402B_D050 – 402B_D05F

402B_D078 – 402B_D07F

402B_D098 – 402B_D09F

402B_D0B8 – 402B_DFFF

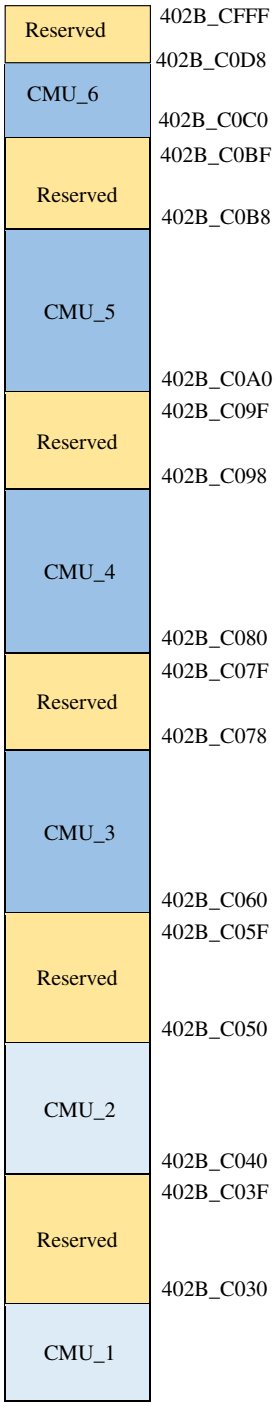

Figure 218. Location of CMUs

55.2 Overview

REG_PROT offers a mechanism to protect defined memory-mapped address locations, in a module under protection, from being written.

REG_PROT is a protection module that is located between the module under protection and the peripheral interface. The address locations to be protected exist in the module under protection and the address locations that can be protected are module specific.

Writes to these protected address locations are locked using a Soft Lock Bit Register (SLBR*n*). Any access to address locations in the module under protection is restricted if their corresponding Soft lock fields in a Soft Lock Bit Register (SLBR*n*) are 1.

The configured soft-lock fields can also be write-restricted by using GCR[HLB]. When GCR[HLB]=1, you cannot write to the soft-lock fields. The address locations in the module under protection can be restricted to Supervisor mode access using GCR[UAA].

55.2.1 Block Diagram

The following figure shows the block diagram of this module.

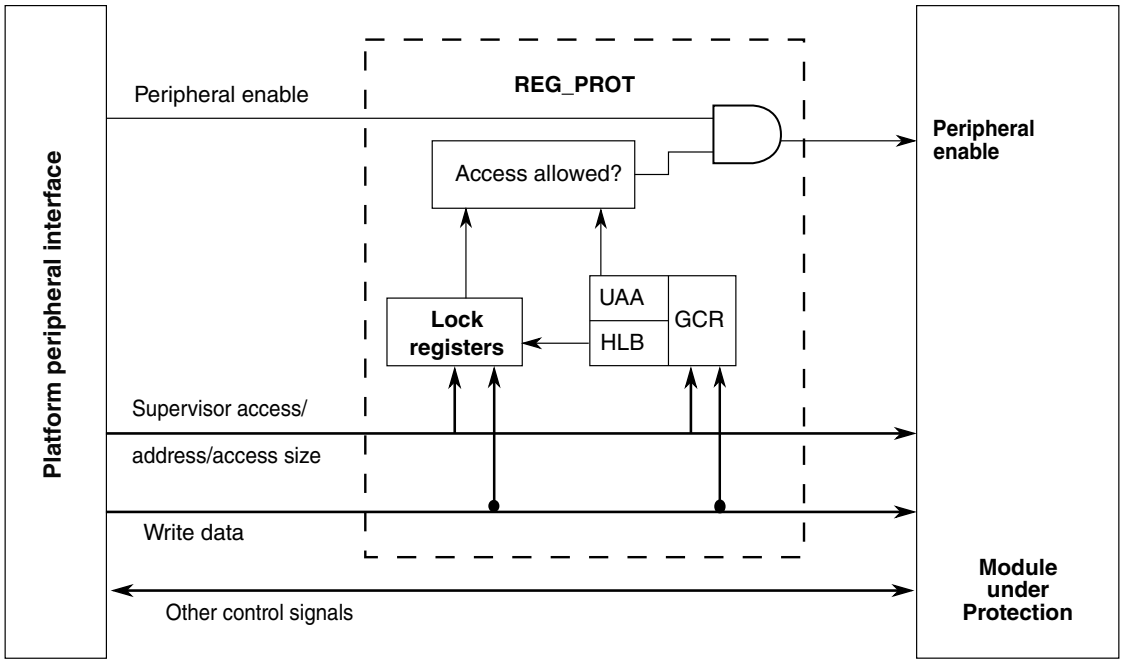

Figure 219. REG_PROT Block diagram

55.2.2 Features

REG_PROT includes these distinctive features:

- Write accesses for the module under protection can be restricted to the supervisor mode only.
- Registers of modules with their register slot size occupying 1 KB to 32 KB of memory-mapped address space, depending on the PROT_MEM parameter, can be dynamically locked. See Memory space and Protection size.
- Multiple ways are present to set the lock bits.
- After the lock bits are configured, they can be protected from changes.

55.3 Functional description

The following sections describe the functional characteristics of the REG_PROT module.

55.3.1 Modes of operation

The mode of REG_PROT depends on the Module Under Protection (MUP). The REG_PROT is operable when the MUP is operable.

The below table shows the write operations in user mode.

Table 318. User mode access table

GCR[UAA]	SLBRn[SLBm]	Write Operation on MUP	Write Operation on REG_PROT
0	0	Transfer error generated, write operation unsuccessful.	Transfer error generated, write operation unsuccessful.
0	1	Transfer error generated, write operation unsuccessful.	Transfer error generated, write operation unsuccessful.
1	0	• If register is implemented and write operation allowed on accessed address location then write operation is successful. • If register is not implemented or write operation is not allowed on accessed address location then transfer error is generated, write operation is unsuccessful.	• If register is implemented and write operation allowed on accessed address location then write operation is successful. • If register is not implemented or write operation is not allowed on accessed address location then transfer error is generated, write operation is unsuccessful.
1	1	Transfer error generated, write operation unsuccessful.	• If register is implemented and write operation allowed on accessed address location then write operation is successful. • If register is not implemented or write operation is not allowed on accessed address location then transfer error is generated.

Note:

- Read operation is always allowed
- n >= 0, m = [0,3]

55.3.2 Memory space and Protection size

This section provides a detailed description of the memory space and protection size of a module using REG_PROT.

The PROT_MEM size varies per chips. It can be:

- 1 KB
- 2 KB
- 4 KB
- 8 KB
- 16 KB
- 32 KB

The resulting memory space is divided into four areas. Memory locations within area #1 and area #2 are a part of the module under protection. Area #3 and area #4 are a part of REG_PROT.

The proper register slot size for each protected module is mentioned in the REG_PROT details file attached to this document.

Following is the memory space for a module that is protected by the REG_PROT module. Reserved registers in area #1 are handled as specified in the protected module's documentation. There is a single register in configuration space that corresponds

to area #4 while the size mentioned in Area size column is to turn the whole area multiple of 4 KB. See the Offset column to know the exact location of the GCR register.

Table 319. Area offset based on protection size

PROT_MEM	Area	Area size	Use	Offset
1 KB	Area 1	1 KB	Module Register(MR0—MR1023)	0000h—03FFh
	Area 2	1 KB	Module Register and Set Soft Lock Bit (LMR0—LMR1023)	0400h—07FFh
	Area 3	256 B	Soft Lock Bit Register (SLBR0—255)	0800h—08FFh
	Area 4	256 B	Global Configuration Register (GCR)	0900h—09FFh
		1.5 KB	Reserved	0A00h— 0FFFh
2 KB	Area 1	2 KB	Module Register (MR0—MR2047)	0000h—07FFh

	Area 3	512 B	Soft Lock Bit Register (SLBR0—511)	1000h—11FFh
	Area 4	256 B	Global Configuration Register (GCR)	1200h—12FFh
		3.25 KB	Reserved	1300h—1FFFh
4 KB	Area 1	4 KB	Module Register (MR0—MR4095)	0000h—0FFFh
	Area 2	4 KB	Module Register and Set Soft Lock Bit (LMR0—LMR4095)	1000h—1FFFh
	Area 3	1 KB	Soft Lock Bit Register (SLBR0—1023)	2000h—23FFh
	Area 4	256 B	Global Configuration Register (GCR)	2400h—24FFh
		6.75 KB	Reserved	2500h—3FFFh
8 KB	Area 1	8 KB	Module Register (MR0—MR8191)	0000h—1FFFh
	Area 2	8 KB	Module Register and Set Soft Lock Bit (LMR0—LMR8191)	2000h—3FFFh
	Area 3	2 KB	Soft Lock Bit Register (SLBR0—2047)	4000h—47FFh
	Area 4	256 B	Global Configuration Register (GCR)	4800h—48FFh
		1.75 KB	Reserved	4900h—4FFFh
16 KB	Area 1	16 KB	Module Register (MR0—MR16383)	0000h—3FFFh
	Area 2	16 KB	Module Register and Set Soft Lock Bit (LMR0—LMR16383)	4000h—7FFFh
	Area 3	4 KB	Soft Lock Bit Register (SLBR0—4095)	8000h—8FFFh
	Area 4	4 KB	Global Configuration Register (GCR)	9000h—9FFFh
32 KB	Area 1	32 KB	Module Register (MR0—MR32767)	0000h—7FFFh
	Area 2	32 KB	Module Register and Set Soft Lock Bit (LMR0—LMR32767)	8000h—FFFFh
	Area 3	8 KB	Soft Lock Bit Register (SLBR0—8191)	10000h—11FFFh
	Area 4	4 KB	Global Configuration Register (GCR)	12000h—12FFFh

- Area #1 can take the memory space of 1 KB/2 KB/4 KB/8 KB/16 KB/32 KB, which holds the normal functional module registers and is transparent for all read/write operations.
- Area #2 can take the memory space of 1 KB/2 KB/4 KB/8 KB/16 KB/32 KB and is a mirror of area #1. For an example, if area #1 takes 8 KB of memory space, then read/write access to an offset 2000+X reads/writes the register at offset X. However, a write access to offset 2000+X additionally sets the optional soft lock bits for this offset X in the same cycle

as the register at offset X is written. This provides for an automatic write and lock operation. Not all registers in area #1 need to have protection defined by the associated soft lock bits. For unprotected registers at offset Y, accesses to offset 2000+Y are identical to accesses at offset Y.

- Area #3 can take the memory space of 256 B/512 B/1 KB/2 KB/4 KB/8 KB and hold soft lock bits, one bit per byte in area #1. The four soft lock bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area #4 can take the memory space of 1.75 KB/3.5 KB/7 KB/2 KB/4 KB/4 KB and holds the configuration bits of the protection mode. There is one configuration Hard lock bit per module that prevents all further modifications to the soft lock bits and can only be cleared by a system reset after it is set. When user access allowed bit is set, it allows user access to the protected module.

If you access a locked byte with a write transaction, a bus error is issued to the system and the write transaction is not executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32—bit registers in area #3 results in a bus transfer error. In area #4, there will not be any transfer error for the address range mentioned in the table above because these address spaces of area #4 are mapped to the GCR register. Accesses in area #4, beyond the address range mentioned in the Module memory map table, are prohibited and might or might not result into a bus abort.

55.3.2.1 Module register (MR)

Each functional module has its own unique set of registers. This chapter refers to these registers generically as module registers (MR), which exist in the lower module memory space (memory area 1), and receive protection from the REG_PROT module.

55.3.2.2 Module Register and Set Soft Lock Bit (LMR)

This is memory area #2 that provides mirrored access to module registers with the side-effect of setting soft lock bits in case of a write access to a register that is defined as protectable by the locking mechanism. Each MR byte is protectable by one associated bit in SLBR*n* [SLB*m*], according to the mapping described in Soft Lock Bit Register (SLBR*n*).

55.3.3 General

This module provides a generic register (address) write-protection mechanism. The register protection size can be:

- 32 bits (address == multiples of 4)
- 16 bits (address == multiples of 2)
- 8 bits (address == multiples of 1)

The addresses that are protected and the register protection size depends on the chip and/or module.

For all addresses that are protected, there are SLBR*n*[SLB*m*] bits that specify whether the address is locked. When an address is locked, it can only be read but not written in any mode (supervisor/normal). If an address is unprotected, the corresponding SLBR*n*[SLB*m*] bit is always 0, regardless of what the software writes to that field.

NOTE

For more information on register protection specification, see the REG_PROT details file attached to this document.

55.3.4 Change lock settings

To change the setting whether an address is locked or unlocked, the corresponding SLBR*n*[SLB*m*] bit needs to be changed. This can be done using the following methods:

- Set the SLBR*n*[SLB*m*] bit(s) by writing to area #2
- Modify the SLBR*n*[SLB*m*] directly by writing to area #3

Both methods are explained in the following sections.

55.3.4.1 Change lock settings via area #2

You can lock a register after writing to it. Note that reading area #2 does not affect soft lock bits. To do so, you must use area # 2.

The following shows an example with PROT_MEM = 8 KB where SLBs are modified using area #2.

When writing 16-bit to address 0008h, MR9 and MR8 in the protected module are updated. The corresponding lock fields remain unchanged (see the left part of Figure 220).

When writing 16-bit to address 2008h, MR9 and MR8 in the protected module are updated. The corresponding lock fields SLBR2[SLB0:1] become 1, and the lock fields SLBR2[SLB2:3] remain unchanged (see the right part of Figure 220).

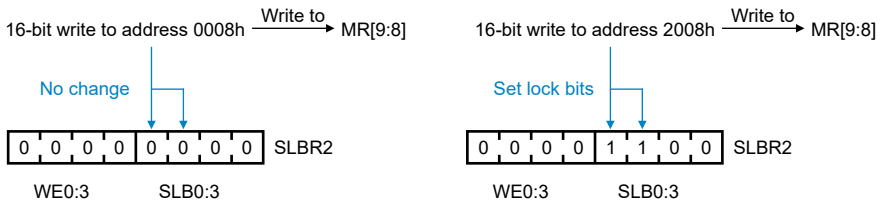

Figure 220. Enable locking via area #2

The following figure shows an example where some addresses are protected and some are not.

In Figure 221, addresses 000Ch and 000Dh are unprotected. Therefore, their corresponding lock fields SLBR3[SLB0:1] are always 0 (shown in bold). During a 32-bit write access to address 200Ch, the lock fields in SLBR3 change as follows:

- SLBR3[SLB2:3] become 1.
- SLBR3[SLB0:1] remain 0.

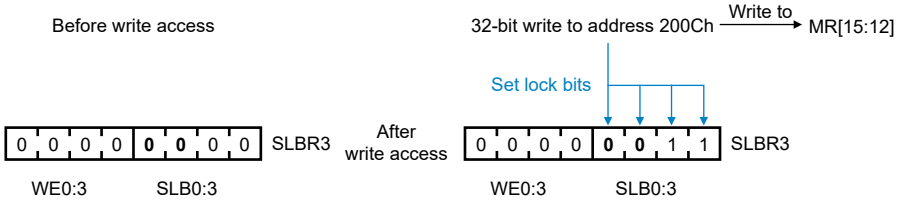

Figure 221. Enable locking for protected and unprotected addresses

55.3.4.2 Change lock settings via area #3

The lock bits are located in area #3 (see Table 319). You can modify them by writing to them. Each SLB*m* field in Soft Lock Bit Register (SLBR*n*) has a mask field, WE*m*, that protects SLB*m* from modification. This masking makes read-modify-write operations unnecessary.

Figure 222 shows two modification examples for registers with 8-bit protection. In part A, a write access to SLBR*n* specifies a mask value that allows modification of all SLBR*n*[SLB0:3] fields. Part B specifies a mask that allows modification only to SLBR*n*[SLB1:3].

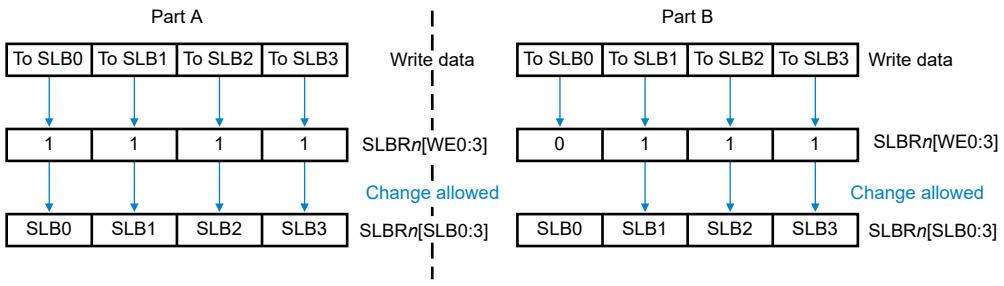

Figure 222. Change lock settings directly via area #3

Figure 223 shows examples for registers with 16-bit protection.

Part A of Figure 223 shows that for SLBR*n*:

- The data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1].
- The data written to SLBR*n*[SLB2] is automatically written to SLBR*n*[SLB3].

This is because the address reflected by SLBR*n*[SLB0] and SLBR*n*[SLB2] are protected 16-bit wise. Note that in this case, the write enable SLBR*n*[WE0] and SLBR*n*[WE2] must be set while SLBR*n*[WE1] and SLBR*n*[WE3] don't matter.

Part B of Figure 223 shows that the data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1]. This is done because the address reflected by SLBR*n*[SLB0] has 16-bit protection. In this case, SLBR*n*[WE0] must be 1 and SLBR*n*[WE1] does not matter. SLBR*n*[SLB2] and SLBR*n*[SLB3] remain unchanged because SLBR*n*[WE2] and SLBR*n*[WE3] are 0.

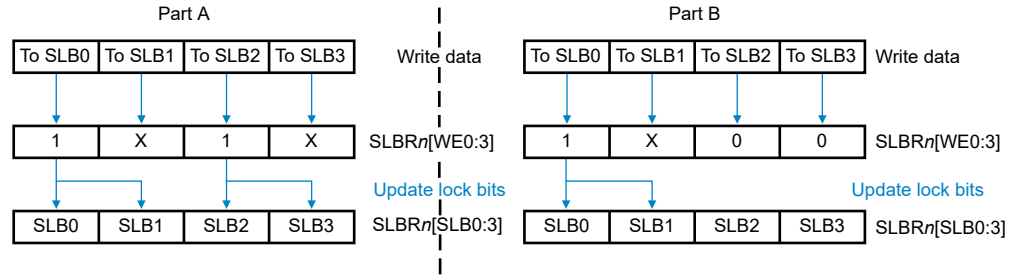

Figure 223. Change lock settings for addresses with 16-bit protection

Figure 224 shows a register with 32-bit protection. In SLBR*n*:

- When SLBR*n*[WE0]=1, the data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1:3] as well.
- When SLBR*n*[WE0]=0, then SLBR*n*[SLB0:3] remain unchanged. Note that in this case, the write enable SLBR*n*[WE0] must be set while SLBR*n*[WE1:3] does not matter.

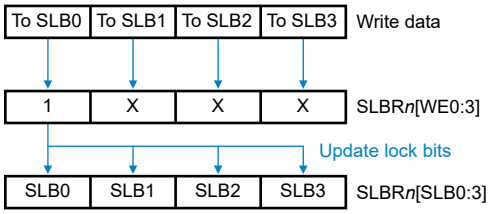

Figure 224. Change lock settings for addresses with 32-bit protection

The following figure shows a mixed protection size configuration.

In SLBR*n*:

- The data written to SLBR*n*[SLB0] is mirrored to SLBR*n*[SLB1] because the corresponding register has 16-bit protection.
- The data written to SLBR*n*[SLB2] is blocked because the corresponding register is unprotected.
- The data written to SLBR*n*[SLB3] is successfully written to SLBR*n*[SLB3] because the corresponding register has 8-bit protection.

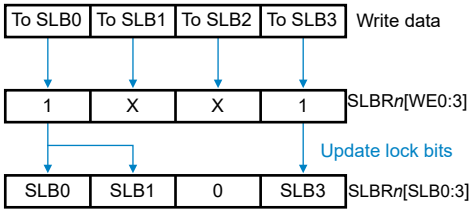

Figure 225. Change lock settings for mixed protection

55.3.4.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in Change lock settings via area #3 and Change lock settings via area #2 is only possible as long as the field GCR.HLB is cleared. After you write 1 to this field, the locking bits cannot be modified until there is a system reset.

55.3.5 Access errors

REG_PROT generates transfer errors under several circumstances, as described below. For the area definition, see Memory space and Protection size.

- If accessing area #1 or area #2, REG_PROT sends any access error from the underlying module under protection.
- If User mode is not allowed, the attempted User mode writes to all areas cause a transfer error, and the writes are blocked.
- If accessing the reserved area, a transfer error is asserted.
- If accessing unimplemented 32-bit registers in areas #3 and #4, a transfer error is asserted.
- If writing to a register in areas #1 and #2, and an SLB field is 1 for any of the affected bytes, then:
  - A transfer error is asserted.
  - The write is blocked.
  - The complete write operation to non-protected bytes in this word is ignored.
- If writing to an SLBR in area #3 with GCR[HLB]=1, a transfer error is asserted.
- Any write operation in any access mode to area #2, when GCR[HLB]=1, is not allowed.

NOTE

The transfer error generated by REG_PROT can only be observed on the CPU that initiates the target register write and has defined the strongly ordered memory region (through its MPU or MMU) covering the target register address.

55.4 External Signals

There are no external signals.

55.5 Initialization

The following sections contain information related to initialization of the Register Protection module.

55.5.1 Sequence

You must configure the REG_PROT first. And then, you need to write 1 to the HLB field in REG_PROT. This ensures that registers under protection are not updated in the user access mode. You need to follow these steps:

1. Enable XRDC protection for the module to enable writes in the supervisor mode only. This step is mandatory, if protected registers of the module are expected to be configured multiple times.
2. Configure REG_PROT to enable write on registers of module under protection.
3. Configure the registers of module under protection.
4. Configure the REG_PROT for the required SLB fields.
5. Set the HLB field in REG_PROT. This step is mandatory, if protected registers of module are expected to be configured only once.

55.5.2 Reset

It is a single clock IP, with single reset.

55.6 REG_PROT register descriptions

This register information documents memory area #3 and area #4.

55.6.1 REG_PROT memory map

REG_PROT base address: base address of protected module instance

Table 320. REG_PROT memory map

PROT_MEM	Offset	Register	Width (In bits)	Access	Reset value

	0x12000 – 0x12FFF	Global Configuration Register (GCR)	32	RW	0000_0000h

55.6.2 Soft Lock Bit Register (SLBR*n*)

Offset

See REG_PROT memory map for SLBR*n* offset ranges. For SLBR*n* addresses, see the REG_PROT details file attached to this document.

Function

These registers hold the Soft Lock Bits (SLBs) for the protected registers in memory area #1, which is the normal register address space of the protected module. Multiple Soft Lock Bit Registers (SLBR*n*) can be implemented, depending on the number of protected module register bytes. Each SLBR*n* has four soft lock fields (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each soft lock field also has a corresponding write enable field in the same register that controls whether the soft lock field can be written. The following table shows the mapping between the soft lock fields to the bytes in memory area #1.

Table 321. SLBs vs. protected address

SLB	Protected address
SLBR0[SLB0]	MR0
SLBR0[SLB1]	MR1
SLBR0[SLB2]	MR2
SLBR0[SLB3]	MR3
SLBR1[SLB0]	MR4
SLBR1[SLB1]	MR5
SLBR1[SLB2]	MR6
SLBR1[SLB3]	MR7
SLBR2[SLB0]	MR8
...	...

WE2	WE2 enables writing to SLB2. 0b - SLB is not modified. 1b - Value is written to SLB.
4 WE3	Write enable bits for SLB WE3 enables writing to SLB3. 0b - SLB is not modified. 1b - Value is written to SLB.
3 SLB0	Soft lock fields for one MRn register SLB0 can block accesses to MR[n *4 + 0]. 0b - Associated MRn byte is unprotected and writable. 1b - Associated MRn byte is locked against write accesses.
2 SLB1	Soft lock bits for one MRn register SLB1 can block accesses to MR[n *4 + 1]. 0b - Associated MRn byte is unprotected and writable. 1b - Associated MRn byte is locked against write accesses.
1 SLB2	Soft lock fields for one MRn register SLB2 can block accesses to MR[n *4 + 2]. 0b - Associated MRn byte is unprotected and writable. 1b - Associated MRn byte is locked against write accesses.
0 SLB3	Soft lock fields for one MRn register SLB3 can block accesses to MR[n *4 + 3]. 0b - Associated MRn byte is unprotected and writable. 1b - Associated MRn byte is locked against write accesses.

55.6.3 Global Configuration Register (GCR)

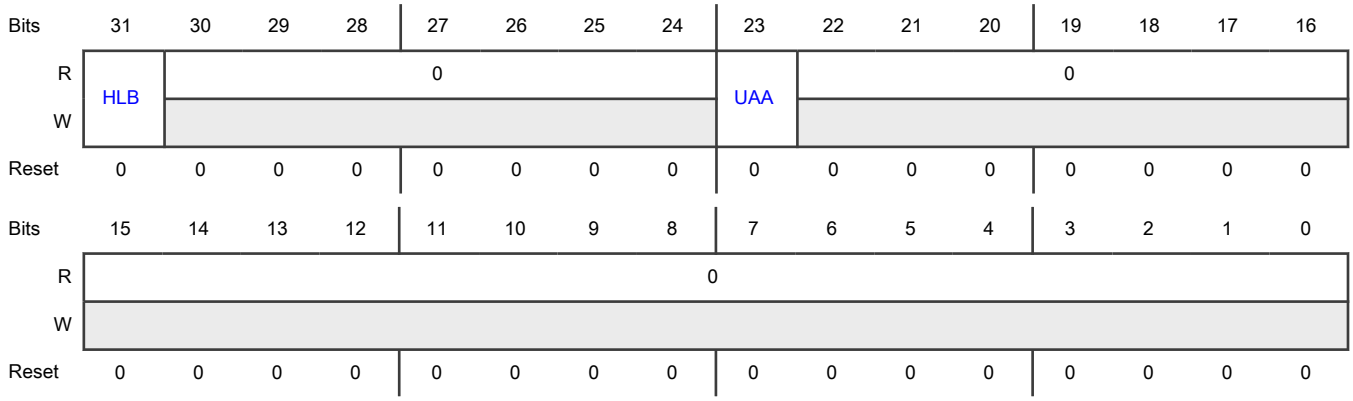
Offset

See REG_PROT memory map for GCR offset.

Function

This register controls module level configurations.

Diagram



Fields

Field	Function
31 HLB	Hard Lock Bit This field cannot be cleared after it is set by the software. It can only be cleared by a system reset. 0b - All SLB fields are accessible and can be modified. 1b - All SLB fields are write protected and cannot be modified. **NOTE** Once this bit is set, it will set all registers under the same PROT_MEM region.
30-24 —	Reserved
23 UAA	User Access Allowed Controls the user and supervisor mode access to registers of the module under protection. 0b - The registers in the module under protection can only be written in the supervisor mode (user access is not allowed). All the write accesses in user (non-supervisor) mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module. 1b - The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. It can be modified in both user (non-supervisor) and supervisory mode.
22-0 —	Reserved

55.7 Glossary

PROT_MEM Integration parameter that specifies the size of the module register slot protected. The PROT_MEM size depends on the chip or module.

Hard lock A lock that restricts access to any register bit. You can unlock or clear this lock through the hardware reset.

Soft lock A lock that restricts access to any register bit. You can unlock or clear this lock through the software.

Chapter 56
Clock Monitoring Unit – Frequency Check (CMU_FC)

56.1 Chip-specific CMU_FC information

56.1.1 CMU_FC configuration

The device consists of a robust clock monitoring architecture targeted to monitor various clock nodes to ensure device clock robustness. There are upto seven clock monitoring units present in the device out of which five are of type CMU_FC. See 'Clock monitoring' section in Clocking chapter for details on device clock monitoring architecture. Register interface clock is referred as 'bus_clock' in the below sections. See Clocking chapter for details.

NOTE

CMU_5 is accessible by Cortex-M0+ core only.

CMU_FC combined spec variation: The combined spec variation for CMU (used for configuring CMU_FCx.HTCR[HFREF] and CMU_FCx.HTCR[LFREF]) is the absolute sum of frequency variations of the clock sources. Refer device datasheet for frequency variations for the corresponding clock sources.

56.2 Overview

CMU_FC ensures the clock integrity of selected clocks and allows continuous clock integrity verification.

CMU_FC checks if the frequency of a monitored clock (*monitored_clock*) is within a programmable frequency range specified by the user. If the frequency is outside the specified limits, it could lead to performance, protocol, and timing failures. CMU_FC requires a clock used as a base reference for the frequency check operation. This reference clock (*reference_clock*) must be within documented limits for correct CMU_FC operation.

56.2.1 Block diagram

CMU_FC counts clock cycles of the monitored clock during a user programmable time duration of *n* clock cycles of the reference clock. There is a comparison between the final count of the monitored clock and the user programmable upper and lower threshold count limits. The control logic determines whether the cycle count is within the programmed limits. If not it sets the Frequency Higher than High frequency reference threshold event status (FHH) field or the Frequency Lower than Low frequency reference threshold event status (FLL) field in the Status Register (SR). If you enable interrupts, an interrupt asserts when the status flag sets.

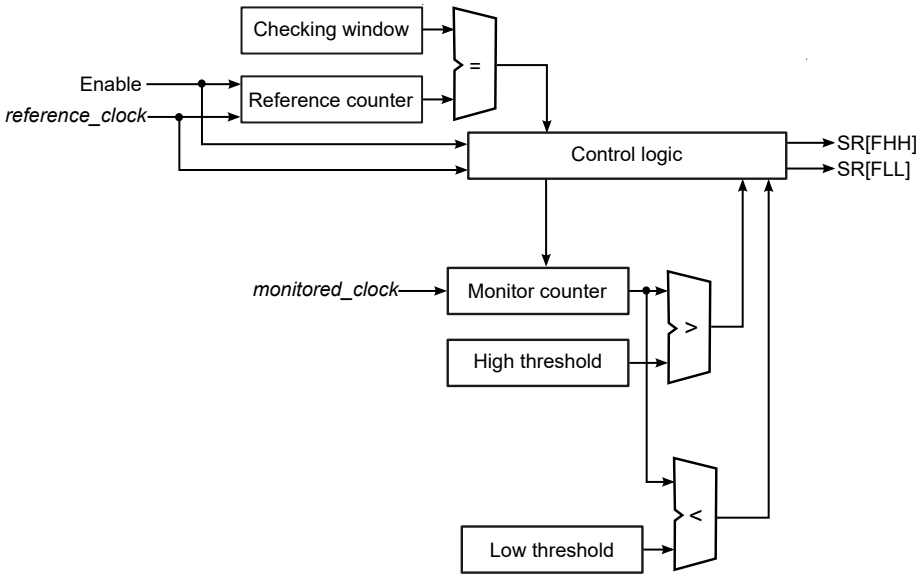


Figure 226. CMU_FC block diagram

CMU_FC cannot detect the following:

- Monitored clock duty cycle variations
- Instantaneous monitored clock frequency variations that do not cross upper or lower threshold limits

56.2.2 Features

The CMU_FC features are:

- Programmable duration of reference clock cycles
- Initiates an event if a monitored clock frequency is higher than high frequency reference (FHH)
- Initiates an event if a monitored clock frequency is lower than low frequency reference (FLL)
- FLL event (if enabled) is generated when monitored clock is very slow or stops functioning
- Masking of FHH event interrupt
- Masking of FLL event interrupt

56.3 Functional description

56.3.1 Operating modes

CMU_FC supports the following operating modes:

- Frequency checking

See the succeeding sections for detailed descriptions of the functions.

56.3.2 Frequency checking

Frequency checking starts when software writes GCR[FCE] = 1. The Run Status field SR[RS] shows 1 after frequency check operation starts.

CMU_FC performs continuous periodic clock checking of the monitored clock. Each checking window involves the following operations:

- Stage 1 – Reference clock counter runs for RCCR[REF_CNT] reference clock cycles. Monitored clock counter runs in parallel for the same time duration as reference clock counter.
- Stage 2 – After stage 1, the module compares the final monitored clock count against the programmed thresholds.

If the monitored clock count is greater than the high threshold value in HTCR[HFREF], an FHH event occurs.

If the monitored clock count is lower than the low threshold value in LTCR[LFREF], an FLL event occurs.

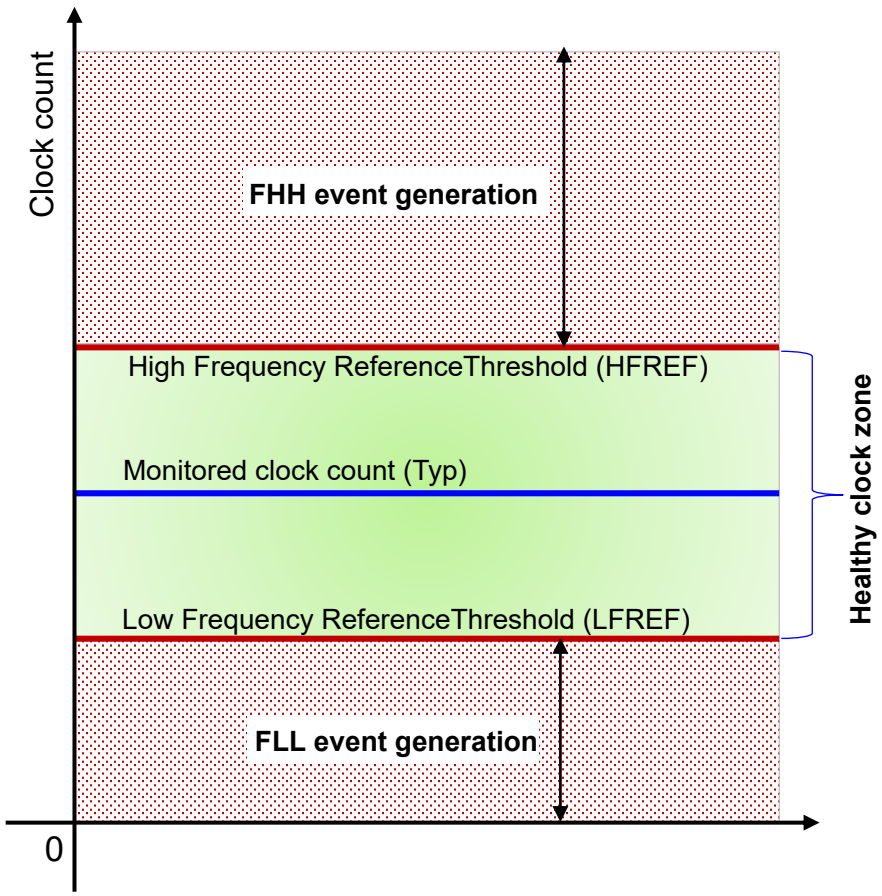

Figure 227. Frequency checking HFREF and LFREF thresholds

56.3.2.1 Monitored clock lost

If a monitored clock ceases operation before evaluation of that clock (Stage 2, see Frequency checking), CMU_FC waits for RCCR[REF_CNT] reference clock periods by extending Stage 2 before triggering an FLL event.

- If *monitored_clock* is not running when enabling CMU_FC:

Worst case FLL response time = (2 × RCCR[REF_CNT] + 12) *reference_clock* cycles + 15 *bus_clock* cycles

- If *monitored_clock* stops when the CMU_FC is running:

Worst case FLL response time = (2 × RCCR[REF_CNT] + 2) *reference_clock* cycles + 3 *bus_clock* cycles

56.3.3 Clocking

This module has the following clock sources.

Table 322. Clock description

Clock	I/O	Description
reference_clock	I	Clock signal that the module uses as a reference to evaluate *monitored_clock*
monitored_clock	I	Clock signal on which frequency check is performed
bus_clock	I	Clock signal on which register read/write operation is performed

NOTE

See the Clocking chapter for details of monitored and reference clocks used on this chip.

56.3.4 Reset

This module has the following reset sources.

- Global hard reset input
- Reset port synchronized to reference clock domain input
- Reset port synchronized to monitored clock domain input

56.4 External signals

This module has no external signals.

56.5 Programming guidelines

56.5.1 Programming RCCR[REF_CNT]

RCCR[REF_CNT] defines the duration of the checking operation in number of *reference_clock* cycles. The minimum RCCR[REF_CNT] value can be calculated using the following formula:

$$\textbf{Minimum RCCR [REF\_CNT]} = \text{CEILING value of MAX}\left(3 \text{ X } \left(\frac{f_{reference\_clock}}{f_{bus\_clock}}\right), 8 + 5 \text{ X } \left(\frac{f_{reference\_clock}}{f_{monitored\_clock}}\right)\right)$$

...where:

- $f_{reference\_clock}$ is the frequency of the reference clock
- f_{bus_clock} is the frequency of the bus clock
- $f_{monitored\_clock}$ is the frequency of the monitored clock

Example to determine RCCR[REF_CNT]:

- f_{bus_clock} = 16 MHz
- $f_{reference\_clock}$ = 8 MHz
- $f_{monitored\_clock}$ = 48 MHz

Formula #1:	$3 \text{ X } \left(\frac{f_{reference\_clock}}{f_{bus\_clock}} \right)$
Inserting the values:	3 × (8 / 16) = 1.5
Formula #2:	$8 + 5 \text{ X } \left(\frac{f_{reference\_clock}}{f_{monitored\_clock}} \right)$
Inserting the values:	8 + 5 × (8 / 48) ≈ 8.83
MAX (1.5, 8.83):	8.83
CEILING value of MAX:	9
Therefore, minimum RCCR[REF_CNT]:	9

Programmed RCCR[REF_CNT] value must be greater than or equal to the calculated minimum value and should be decided after considering application requirements of frequency check completion response time and overall accuracy required from CMU_FC.

- Higher values of RCCR[REF_CNT] results in longer measurement window, leading to better accuracy in monitored clock check.
- Lower values of RCCR[REF_CNT] results in shorter measurement window, leading to faster FHH and FLL event response, but higher inaccuracy in reported result.

For measurement window calculation, see step 8 in Programming HFREF and LFREF

56.5.2 Programming HFREF and LFREF

You must consider the following when programming HFREF/LFREF:

- Tolerable monitored clock frequency variation
- Maximum reference clock frequency variation
- Inherent module inaccuracy

CMU_FC has an expected maximum deviation of ± 3 *monitored_clock* cycles (CMU_FC_{VAR+} = 3, CMU_FC_{VAR-} = –3).

The following procedure shows how to calculate optimum values for HTCR[HFREF] and LTCR[LFREF] (numbers shown are from example in table):

1. Determine the ideal *monitored_clock* frequency ($f_{monitored\_clock}$ (ideal), 48 MHz).
2. Determine the specified variation of the *monitored_clock* (1.1%).
3. Calculate *monitored_clock* frequency variation: .

   $$f_{monitored\_clock}\,(ideal) \text{ X} \left(1 \pm variation\ (\text{step 2})\right)$$

   - $f_{monitored\_clock}$ (max) = 48 MHz × (1 + (1.1 ÷ 100)) = 48.53 MHz
   - $f_{monitored\_clock}$ (min)= 48 MHz × (1 – (1.1 ÷ 100)) = 47.47 MHz
4. Determine the ideal *reference_clock* frequency ($f_{reference\_clock}$ (ideal), 8 MHz).
5. Determine the specified variation of the *reference_clock* (3.3%).

6. Calculate ideal *reference_clock* frequency variation:

$$f_{reference\_clock}\ (ideal) \times (1 \pm variation\ (\text{step 5}))$$

   - $f_{reference\_clock}$ (max) = 8 MHz × (1 + (3.3 ÷ 100)) = 8.26 MHz
   - $f_{reference\_clock}$ (min) = 8 MHz × (1 – (3.3 ÷ 100)) = 7.74 MHz
7. Select the value of RCCR[REF_CNT] needed (80). See Programming RCCR[REF_CNT].
8. Calculate ideal measurement window:

$$\frac{RCCR\,[REF\_CNT]}{f_{reference\_clock}\ (ideal)}$$

   - 80 ÷ 8 MHz = 10000 ns
9. Calculate ideal *monitored_clock* count:

$$\frac{RCCR[REF\_CNT]}{f_{reference\_clock}(ideal)} \times f_{monitored\_clock}\ (ideal)$$

   - 80 ÷ 8 MHz × 48 MHz = 480.00 (round off this value, 480 in this case)
10. Calculate high threshold value (HTCR[HFREF]):

$$\text{Ceiling value of } \left(\frac{f_{monitored\_clock}\ (max)}{f_{reference\_clock}\ (min)} \times RCCR[REF\_CNT]\right) + CMU\_FC_{VAR+}$$

    - HTCR[HFREF] = Ceiling(48.53 MHz ÷ 7.74 MHz × 80 + 3) = 505
11. Calculate low threshold value (LTCR[LFREF]):

$$\text{Floor value of } \left(\frac{f_{monitored\_clock}\ (min)}{f_{reference\_clock}\ (max)} \times RCCR[REF\_CNT]\right) - CMU\_FC_{VAR-}$$

    - LTCR[LFREF] = Floor(47.47 MHz ÷ 8.26 MHz × 80 – 3) = 456

Table 323. HTCR[HFREF] and LTCR[LFREF] calculation example

Property	Value	Unit
Bus clock frequency (f_{bus_clock})	16	MHz
Monitored clock frequency ($f_{monitored\_clock}$ (ideal))	48	MHz
Specified variation of monitored clock	1.1	%
Monitored clock frequency (maximum after specified variation, $f_{monitored\_clock}$ (max))	48.53	MHz

Table continues on the next page...

Table 323. HTCR[HFREF] and LTCR[LFREF] calculation example (continued)

Property	Value	Unit
Monitored clock frequency (minimum after specified variation, $f_{monitored\_clock}$ (min))	47.47	MHz
Reference clock frequency ($f_{reference\_clock}$ (ideal))	8	MHz
Specified variation of reference clock	3.3	%
Reference clock frequency (maximum after specified variation, $f_{reference\_clock}$ (max))	8.26	MHz
Reference clock frequency (minimum after specified variation, $f_{reference\_clock}$ (min))	7.74	MHz
Minimum reference count (RCCR[REF_CNT])	9	—
Programmed reference count (RCCR[REF_CNT]) (must be ≥ minimum RCCR[REF_CNT])	80	—
Measurement window	10000.00	ns
Calculated monitored clock count	480.00	—
Calculated monitored clock Count (rounded)	480	—
Module positive variation (CMU_FC_{VAR+})	3	—
Module negative variation (CMU_FC_{VAR-})	-3	—
Programmed higher threshold (HTCR[HFREF])	505	—
Programmed lower threshold (LTCR[LFREF])	456	—

56.5.3 Module programming sequence

56.5.3.1 Module programming sequence

The recommended programming sequence for CMU_FC frequency checking is:

1. In any order, complete the following:
   - Program RCCR[REF_CNT] to define the frequency measuring window duration in *reference_clock* cycles.
   - Program LTCR[LFREF] and HTCR[HFREF] to set the permissible frequency range of the *monitored_clock*.
   - Program IER to enable interrupt.
2. Write GCR[FCE] = 1 to start the frequency check operation.

   NOTE

   When GCR[FCE] = 1, you must not write to RCCR, HTCR, LTCR, or IER. Attempting to do so generates a bus transfer error.
3. To reconfigure RCCR, LTCR, HTCR , and IER or to stop frequency check operation, wait for SR[RS] = 1, then write GCR[FCE] = 0.

56.6 CMU_FC register descriptions

56.6.1 CMU_FC memory map

This section describes the address order of all the CMU_FC registers. Each description includes a standard register diagram and associated field descriptions.

CMU_0 base address: 402B_C000h

CMU_3 base address: 402B_C060h

CMU_4 base address: 402B_C080h

CMU_5 base address: 402B_C0A0h

CMU_6 base address: 402B_C0C0h

Offset	Register	Width (In bits)	Access	Reset value
0h	Global Configuration Register (GCR)	32	RW	0000_0000h
4h	Reference Count Configuration Register (RCCR)	32	RW	0000_0000h
8h	High Threshold Configuration Register (HTCR)	32	RW	00FF_FFFFh
Ch	Low Threshold Configuration Register (LTCR)	32	RW	0000_0000h
10h	Status Register (SR)	32	RW	0000_0000h
14h	Interrupt Enable Register (IER)	32	RW	0000_0000h

56.6.2 Global Configuration Register (GCR)

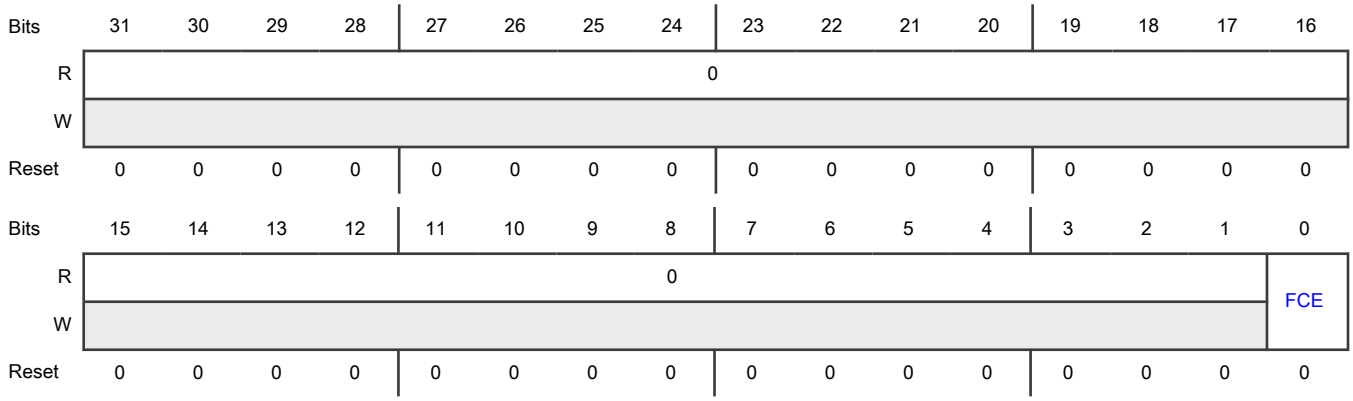
Offset

Register	Offset
GCR	0h

Function

Controls module level configurations such as enabling frequency check.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 FCE	Frequency Check Enable Starts or stops frequency checking. FCE is disabled by default. Software can enable FCE at any time. To stop the ongoing operation, write 0 to FCE only when SR[RS] = 1. 0b - Stops frequency checking 1b - Starts frequency checking

56.6.3 Reference Count Configuration Register (RCCR)

Offset

Register	Offset
RCCR	4h

Function
Programs reference count duration of the frequency check window.

NOTE
Write to RCCR only when GCR[FCE] = 0. A bus transfer error results if software writes RCCR when GCR[FCE] = 1.

Diagram

23-0 LFREF	Low Frequency Reference Threshold LFREF determines the low reference value for the monitored clock frequency. See Programming HFREF and LFREF for LFREF calculation. **NOTE** Do not program LFREF to a value less than 0x00000003.

56.6.6 Status Register (SR)

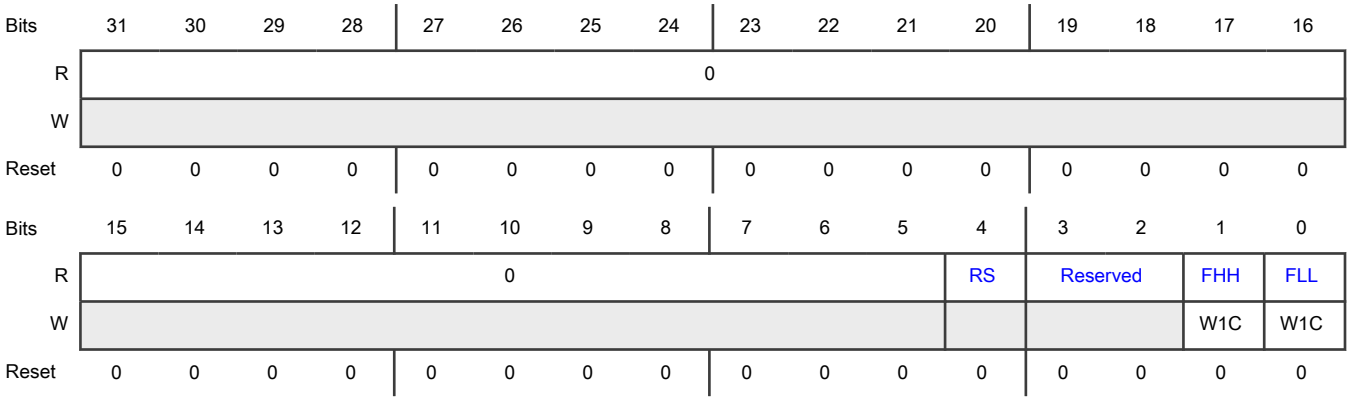
Offset

Register	Offset
SR	10h

Function

Provides the internal status of the module.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 RS	Run Status Shows the running status of module internal operation. After enabling the frequency check operation (GCR[FCE] = 1), there is a fixed delay before this field shows running status. If the system wants to disable the frequency check operation, then the software should read this register and write GCR[FCE] = 0 only when this field is 1. 0b - Frequency check stopped 1b - Frequency check running
3-2 —	Reserved
1 FHH	Frequency higher than high frequency reference threshold event status Hardware writes 1 to FHH when the monitored clock frequency becomes higher than the high threshold value in HTCR[HFREF]. FHH clears when software writes 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No FHH event 1b - FHH event occurred
0 FLL	Frequency lower than low frequency reference threshold event status Hardware writes 1 to FLL when the monitored clock frequency becomes lower than the low threshold value in LTCR[LFREF]. FLL clears when software writes 1. 0b - No FLL event 1b - FLL event occurred

56.6.7 Interrupt Enable Register (IER)

Offset

Register	Offset
IER	14h

Function

Enables CMU_FC interrupts.

NOTE

Write IER only when GCR[FCE] = 0. A bus transfer error results if software writes IER when GCR[FCE] = 1.

Enable only either asynchronous FHH event interrupt or synchronous FHH event interrupt at a time.

For example:

- If IER[FHHIE] is set to 1 then set IER[FHHAIE] to 0.
- If IER[FHHAIE] is set to 1 then set IER[FHHIE] to 0.

Enable only either asynchronous FLL event interrupt or synchronous FLL event interrupt at a time.

For example:

- If IER[FLLIE] is set to 1 then set IER[FLLAIE] to 0.
- If IER[FLLAIE] is set to 1 then set IER[FLLIE] to 0.

See Clocking chapter for interrupt usage information based on CMU_FC instances.

56.7 Glossary

FHH The state that the monitored clock frequency is higher than the high frequency reference. FHH is also the name of the register field that indicates this state.

FHH event The event that the module triggers when it detects FHH.

FLL The state that the monitored clock frequency is lower than the lower frequency reference. FLL is also the name of the register field that indicates this state.

FLL event The event that the module triggers when it detects FLL.

Chapter 57
Clock Monitoring Unit – Frequency Meter (CMU_FM)

57.1 Chip-specific CMU_FM information

57.1.1 CMU_FM configuration

The device consists of a robust clock monitoring architecture targeted to monitor various clock nodes to ensure device clock robustness. There are upto seven clock monitoring units present in the device out of which 2 are of type CMU_FM. See 'Clock monitoring' section in Clocking chapter for details on device clock monitoring architecture. Register interface clock is referred as 'bus_clock' in the below sections. See Clocking chapter for details.

NOTE

CMU metering interrupt is not generated if the clock which is being metered is lost. A timeout status flag, CMU.SR[FMTO] is updated in this case.

NOTE

Software must ensure that CMU1 interrupt is serviced within POR_WDG timeout. In absence of CMU1 interrupt servicing, the POR_WDG detects this as an FIRC failure and initiates a POR recovery.

57.2 Overview

CMU_FM measures the frequency of the metered clock (*metered_clock*) using another clock as reference. This reference clock (*reference_clock*) must be within documented limits for correct CMU_FM operation. CMU_FM operation is only guaranteed if a reference clock is within normal operating parameters.

57.2.1 Block diagram

The CMU_FM counts the clock cycles of a metered clock in the user programmable time duration *n* number of clock cycles of the reference clock. After completion of a metered clock operation, a register field sets, indicating the operation has completed. The count of the metered clock also updates in the Status Register (SR) after completion of a metered clock operation.

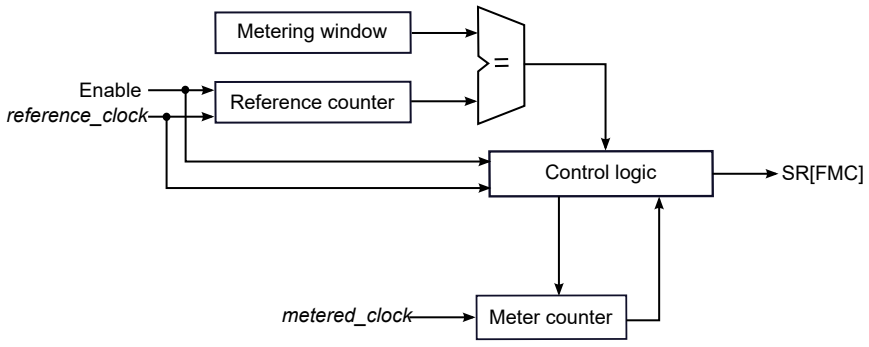

Figure 228. Block diagram

57.2.2 Features

Features of the CMU_FM are:

- Programmable duration of *reference_clock* cycles
- Maskable interrupt generation when frequency metering completes

- Timeout feature indicates loss of *metered_clock*

57.3 Functional description

The frequency meter operation initiates when software writes GCR[FME] = 1. When the operation starts, hardware writes SR[RS] = 1. Safety critical applications must poll SR[RS] to determine when metering operation starts.

Frequency metering window involves these operations:

1. Stage 1 — The reference clock counter runs for RCCR[REF_CNT] cycles of *reference_clock*. The metered clock counter runs in parallel for the same time duration as the *reference_clock* counter.
2. Stage 2 — At the end of stage 1, SR[FMC] = 1, SR[MET_CNT] updates with the *metered_clock* count, and CMU_FM writes GCR[FME] = 0.

57.3.1 Clocking

The following table lists the clock sources for this module.

Table 324. Clock description

Clock	I/O	Description
reference_clock	I	Clock signal that the module uses as a reference to evaluate *metered_clock*
metered_clock	I	Clock signal on which frequency metering is performed
bus_clock	I	Clock signal on which register read/write operation is performed

NOTE

See the Clocking chapter for details of metered and reference clocks used on this chip.

57.3.2 Reset

This module has the following reset sources.

- Global hard reset input
- Reset port synchronized to reference clock domain input
- Reset port synchronized to monitored clock domain input

57.4 Programming guidelines

57.4.1 Programming RCCR[REF_CNT]

RCCR[REF_CNT] defines the duration of the metering operation in number of *reference_clock* cycles. The minimum RCCR[REF_CNT] value can be calculated using the following formula:

$$\textbf{Minimum RCCR [REF\_CNT]} = \text{CEILING value of MAX}\left(3 \text{ X } \left(\frac{f_{reference\_clock}}{f_{bus\_clock}}\right), 8 + 5 \text{ X } \left(\frac{f_{reference\_clock}}{f_{monitored\_clock}}\right)\right)$$

...where:

- $f_{reference\_clock}$ is the frequency of the reference clock
- f_{bus_clock} is the frequency of the bus clock

- $f_{metering\_clock}$ is the frequency of the metered clock

Example to determine RCCR[REF_CNT]:

- f_{bus_clock} = 16 MHz
- $f_{reference\_clock}$ = 8 MHz
- $f_{metered\_clock}$ = 48 MHz

Formula #1:	$3 X \left(\frac{f_{reference\_clock}}{f_{bus\_clock}} \right)$
Inserting the values:	3 × (8 / 16) = 1.5
Formula #2:	$8 + 5 X \left(\frac{f_{reference\_clock}}{f_{monitored\_clock}} \right)$
Inserting the values:	8 + 5 × (8 / 48) ≈ 8.83
MAX (1.5, 8.83):	8.83
CEILING value of MAX:	9
Therefore, minimum RCCR[REF_CNT]:	9

Programmed RCCR[REF_CNT] value must be greater than or equal to the calculated minimum value and should be decided after considering application requirements of frequency metering completion response time and overall accuracy required from CMU_FM.

- Higher values of RCCR[REF_CNT] results in longer metering window, leading to better accuracy in metered clock measurement.
- Lower values of RCCR[REF_CNT] results in shorter metering window, leading to faster FMC response, but higher inaccuracy in reported result.

57.4.2 Module programming sequence

The recommended programming sequence of CMU_FM is:

1. In any order, complete the following:
   - Program RCCR[REF_CNT] to define the frequency metering window duration in *reference_clock* cycles.
   - Program IER[FMCIE] to enable interrupt.
2. Write GCR[FME] = 1 to start frequency metering operation. Writes to RCCR and IER are disabled after GCR[FME] = 1. Attempting a write to any of them after GCR[FME] = 1 generates a bus transfer error.
3. To reconfigure RCCR and IER or to stop frequency metering operation, wait for SR[RS] = 1, then write GCR[FME] = 0.

Upon completion of metering operations:

- Hardware writes SR[FMC] = 1
- SR[MET_CNT] updates with metered count value
- Hardware writes GCR[FME] = 0

57.5 External signals

This module has no external signals.

57.6 CMU_FM register descriptions

57.6.1 CMU_FM memory map

This section describes the address order of all the CMU_FM registers. Each description includes a standard register diagram and associated field descriptions.

CMU_1 base address: 402B_C020h

CMU_2 base address: 402B_C040h

Offset	Register	Width (In bits)	Access	Reset value
0h	Global Configuration Register (GCR)	32	RW	0000_0000h
4h	Reference Count Configuration Register (RCCR)	32	RW	0000_0000h
8h	Status Register (SR)	32	RW	0000_0000h
Ch	Interrupt Enable Register (IER)	32	RW	0000_0000h

57.6.2 Global Configuration Register (GCR)

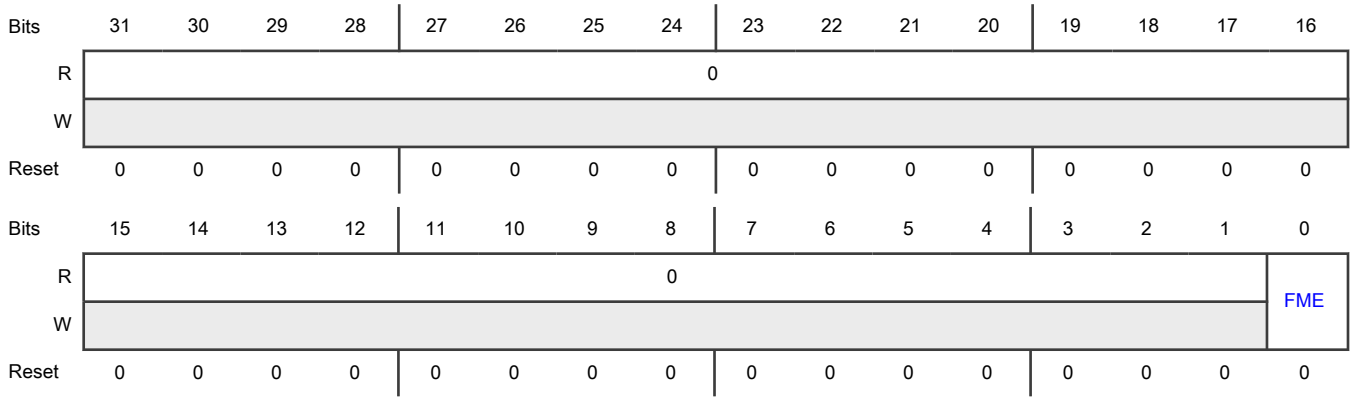
Offset

Register	Offset
GCR	0h

Function

Controls module level configurations such as enabling frequency metering.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 FME	Frequency Meter Enable Starts or stops frequency metering. FME is disabled by default. Software can enable FME at any time. To stop the ongoing operation, write 0 to FME only when SR[RS] = 1. FME automatically clears upon frequency metering completion or timeout event. 0b - Stops frequency metering 1b - Starts frequency metering

57.6.3 Reference Count Configuration Register (RCCR)

Offset

Register	Offset
RCCR	4h

Function

Programs reference count duration of the frequency meter window.

NOTE

Write to RCCR only when GCR[FME] = 0. A bus transfer error results if software writes RCCR when GCR[FME] = 1.

Diagram

Fields

Field	Function
31-8 MET_CNT	Meter Clock Count This field stores the count value of the metered clock cycles when frequency metering operation is complete, in other words, SR[FMC] = 1. CMU_FM has a maximum deviation of ± 3 *metered_clock* cycles over the ideal *metered_clock* cycles expected by the user.
7-5 —	Reserved
4	Run Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
RS	Shows the running status of module internal operation. After enabling the frequency metering operation (GCR[FME] = 1), there is a fixed delay before this field shows running status. If the system wants to disable the frequency metering operation, then the software should read this register and write GCR[FME] = 0 only when this field is 1. 0b - Frequency meter stopped 1b - Frequency meter running
3-2 —	Reserved
1 FMTO	Frequency Meter Time Out Sets if there is a loss of metered clock during the metering operation. After metering window, the module waits for a timeout duration of RCCR[REF_CNT] cycles before writing one to this field. GCR[FME] = 0 and SR[FMC] = 0 when FMTO = 1. Writing one clears this field.
0 FMC	Frequency Meter Operation Complete On completion of frequency metering operation, FMC = 1, SR[MET_CNT] field updates, and GCR[FME] clears. Writing one clears this field.

57.6.5 Interrupt Enable Register (IER)

Offset

Register	Offset
IER	Ch

Function

Enables CMU_FM interrupts.

NOTE

Write IER only when GCR[FME] = 0. A bus transfer error results if software writes IER when GCR[FME] = 1.

Diagram

Chapter 58
Cyclic Redundancy Check (CRC)

58.1 Chip-specific CRC information

This chip supports one instance of CRC module.

58.2 Overview

CRC generates 16-bit or 32-bit CRC codes output for error detection. You can calculate these codes for up to 32 bits input data at a time.

CRC provides a programmable polynomial and other parameters to meet 16-bit or 32-bit CRC standards.

58.2.1 Block diagram

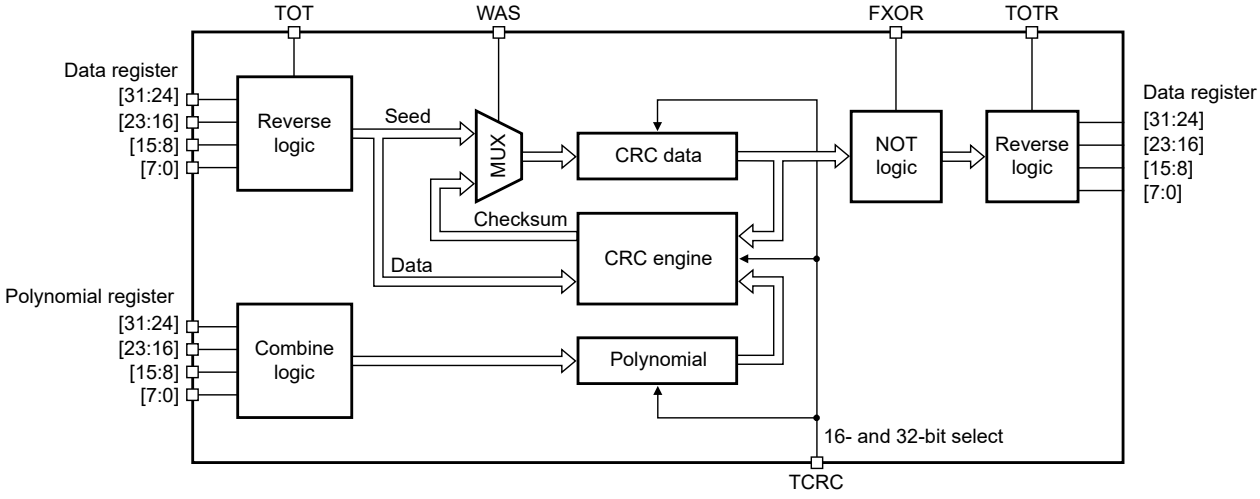

Figure 229. Block diagram

58.2.2 Features

CRC has the following features:

- Hardware CRC generator circuit using 16-bit or 32-bit programmable shift registers
- Programmable initial seed value and polynomial
- Transpose of input or output data (CRC result) in bitwise or bytewise (this option is required for certain CRC standards. You cannot perform a bytewise transpose operation when accessing DATA via 8-bit access.)
- Invert final CRC result
- 32-bit CPU register programming interface

58.3 Functional description

58.3.1 Modes of operation

The following sections describe various modes of operation that affect the functionality of CRC: Run mode and Low power mode.

58.3.1.1 Run mode

Run mode is the basic mode of operation.

58.3.1.2 Low power mode

When the chip enters the lower power mode, the CRC module clock (ipg_clk and ipg_clk_s) is disabled and the in-progress CRC calculation stops. The calculation resumes after the CRC module clock is enabled or the chip exits low power mode via system reset.

58.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, you can program data values as 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes lead to an incorrect CRC calculation.

58.3.2.1 Calculating a 16-bit CRC

Perform these steps to calculate a 16-bit CRC:

1. Write 0 to CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in Data (DATA) as required for the CRC calculation.
3. Write a 16-bit polynomial to GPOLY[LOW].

   GPOLY[HIGH] is not usable in 16-bit CRC mode.
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to DATA[LU] and DATA[LL].

   DATA[HU] and DATA[HL] are not used.
6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values into DATA[LU], and DATA[LL]

   CRC is calculated on every data value write and the intermediate CRC result is stored back into DATA[LU] and DATA[LL]
8. After writing all the data values, read the final CRC result from DATA[LU] and DATA[LL].

CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

58.3.2.2 Calculating a 32-bit CRC

Perform these steps to calculate a 32-bit CRC:

1. Write 1 to CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in Control (CTRL) as required for CRC calculation. See Transpose feature and Result complement for details.
3. Write a 32-bit polynomial to GPOLY[HIGH] and GPOLY[LOW] .
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to DATA[HU], DATA[HL], DATA[LU], and DATA[LL].
6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values into DATA[HU], DATA[HL], DATA[LU], and DATA[LL]

   CRC is computed on every data value write and the intermediate CRC result is stored back into DATA[LU] and DATA[LL]
8. After writing all the values, read the final CRC result from DATA[HU], DATA[HL], DATA[LU], and DATA[LL].

CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

58.3.3 Transpose feature

Transpose is not enabled by default. However, CRC requires input data and/or final checksum to be transposed. You have an option to configure each transpose operation separately to meet CRC standards. The data is transposed on-the-fly while being read or written.

Some protocols use the little-endian format for data stream to calculateCRC. In this case, transpose flips bits.

58.3.3.1 Types of transpose

CRC provides several types of transpose to flip bits and/or bytes for both writing input data and reading result separately using the CTRL[TOT] and CTRL[TOTR] according to the CRC calculation being used.

The following types of transpose are available for writing to and reading from DATA.

1. CTRL[TOT] or CTRL[TOTR] is 0.

   No transposition occurs.

2. CTRL[TOT] or CTRL[TOTR] is 1.

   Bits in a byte are transposed when bytes are not transposed.

   reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}.

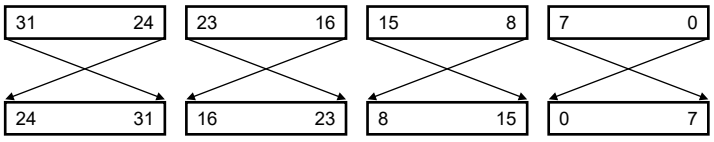

Figure 230. Transpose type 1b

3. CTRL[TOT] or CTRL[TOTR] is 10b.

   Both bits in bytes and bytes are transposed.

   reg[31:0] becomes {reg[0:7], reg[8:15], reg[16:23], reg[24:31]}.

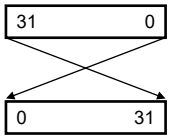

Figure 231. Transpose type 10b

4. CTRL[TOT] or CTRL[TOTR] is 11b.

   Bytes are transposed but bits are not transposed.

   reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}.

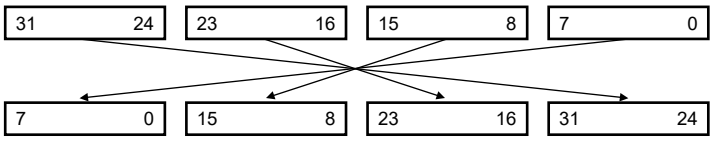

Figure 232. Transpose type 11b

NOTE

For 8-bit and 16-bit write accesses to Data (DATA), the data is transposed with 0s on the unused byte or bytes (taking 32 bits as a whole), but CRC is calculated on the valid byte(s) only. When reading the Data (DATA) for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in DATA[HU] and DATA[HL]. You must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

58.3.4 Result complement

When CTRL[FXOR] = 1, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in Data (DATA) every time Data (DATA) is read. When CTRL[FXOR] = 0,, reading Data (DATA) accesses the raw checksum value.

58.3.5 Clocking

Table 325. CRC clocks

Type of clock	Description
Bus clock (ipg_clk/ipg_clk_s)	ipg_clk_s controls the access to the CRC registers. ipg_clk and ipg_clk_s function the CRC module.

58.3.6 Interrupts

This module has no interrupts.

58.4 External signals

There is no CRC signal that connects off chip.

58.5 Initialization

To enable CRC calculation, you must program:

- CTRL[WAS] .
- Polynomial (GPOLY).
- Parameters for transposition and CRC result inversion in the applicable registers.

Writing 1 to CTRL[WAS] enables you to program the seed value into CRC Data registers.

After writing all the data, you must wait for at least two clock cycles to read the data from CRC Data (DATA) register.

After a CRC calculation completes, you can reinitialize the module for a new CRC computation by again writing 1 to CTRL[WAS] and programming a new, or previously used, seed value. You must set all other parameters before programming the seed value and subsequent data values.

58.6 Use cases

The following tables use the little-endian format.

58.6.1 CTRL programming

The following table shows Control (CTRL) programming for 16-bit CRC.

Table 326. CTRL programming for 16-bit CRC

Algorithm	Polynomial	Seed	Ref in	Ref out	XOR out	CTRL[TOT]	CTRL[TOTR]	CTRL[FXOR]

58.7 Memory map and register descriptions

NOTE

You must reconfigure CRC engine in case an IPS transfer error occurs (ips_xfr_err).

The CRC module generates a transfer error in the following cases:

- Write accesses to the register addresses that are not mapped to the peripherals but included in the address spaces of the peripherals.

58.7.1 CRC register descriptions

58.7.1.1 CRC memory map

CRC base address: 4038_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Data (DATA)	32	RW	FFFF_FFFFh
4h	Polynomial (GPOLY)	32	RW	0000_1021h
8h	Control (CTRL)	32	RW	0000_0000h

58.7.1.2 Data (DATA)

Offset

Register	Offset
DATA	0h

Function

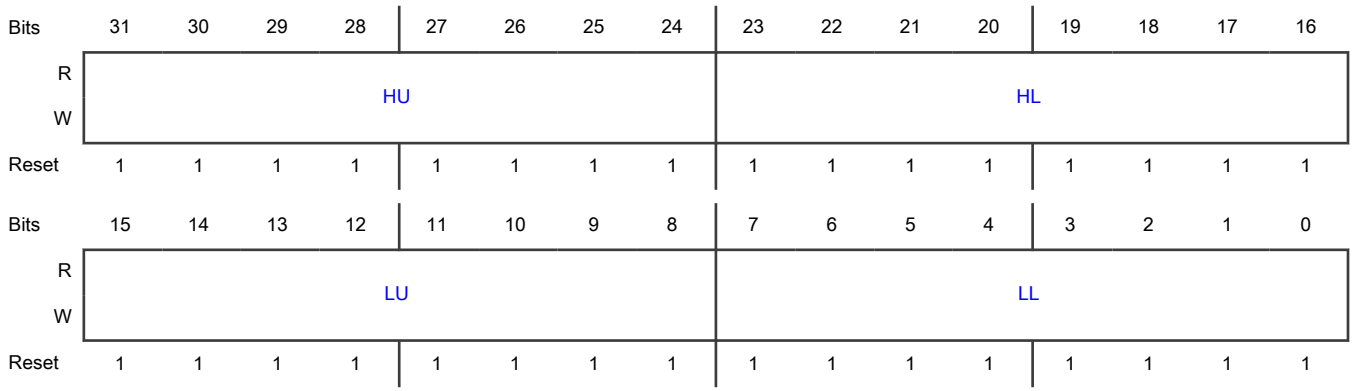
Configures the value of seed, data, and checksum. When CTRL[WAS] = 1, any write to this register is regarded as the seed value. When CTRL[WAS] becomes 0, any write to this register is regarded as data for general CRC calculation.

In 16-bit CRC mode, DATA[HU] and DATA[HL] are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, you can program to write 8 bits, 16 bits, or 32 bits in big endian order, provided all bytes are contiguous.

After writing all data values, you can read the CRC result from DATA register. In 16-bit CRC mode, the CRC result is available in DATA[LU] and DATA[LL]. In 32-bit CRC mode, all fields contain the result. After writing all data, you must wait for at least two clock cycles to read the data from CRC data (DATA) register.

Diagram



Fields

Field	Function
31-24 HU	Upper Part of High Byte Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 0. • In 16-bit CRC mode (CTRL[TCRC] = 0), this field is not used for programming a seed value. • In 32-bit CRC mode (CTRL[TCRC] = 1), the values written to this field are part of the seed value when CTRL[WAS] = 1.
23-16 HL	Lower Part of High Byte Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 1. • In 16-bit CRC mode (CTRL[TCRC] = 0), this field is not used for programming a seed value. • In 32-bit CRC mode (CTRL[TCRC] = 1), the values written to this field are part of the seed value when CTRL[WAS] = 1.
15-8 LU	Upper Part of Low Byte Generates CRC checksum when CTRL[WAS] = 0. When CTRL[WAS] = 1,the values written to this field are part of the seed value.
7-0	Lower Part of Low Byte

Table continues on the next page...

Table continued from the previous page...

Field	Function
LL	Generates CRC checksum when CTRL[WAS] = 0. When CTRL[WAS] = 0, the values written to this field are part of the seed value.

58.7.1.3 Polynomial (GPOLY)

Offset

Register	Offset
GPOLY	4h

Function

Configures polynomial value for CRC calculation.

- Sets the upper 16 bits of polynomial that are used only in 32-bit CRC mode. Writes to this field are ignored in 16-bit CRC mode.
- Sets the lower 16 bits of polynomial that are used in both 16-bit and 32-bit CRC modes.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	HIGH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LOW															
Reset	0	0	0	1	0	0	0	0	0	0	1	0	0	0	0	1

Fields

Field	Function
31-16 HIGH	High Half-Word Writable and readable in 32-bit CRC mode (CTRL[TCRC] = 1). You cannot write to this field in 16-bit CRC mode (CTRL[TCRC] = 0).
15-0 LOW	Low Half-Word Writable and readable in both 16-bit and 32-bit CRC modes.

58.7.1.4 Control (CTRL)

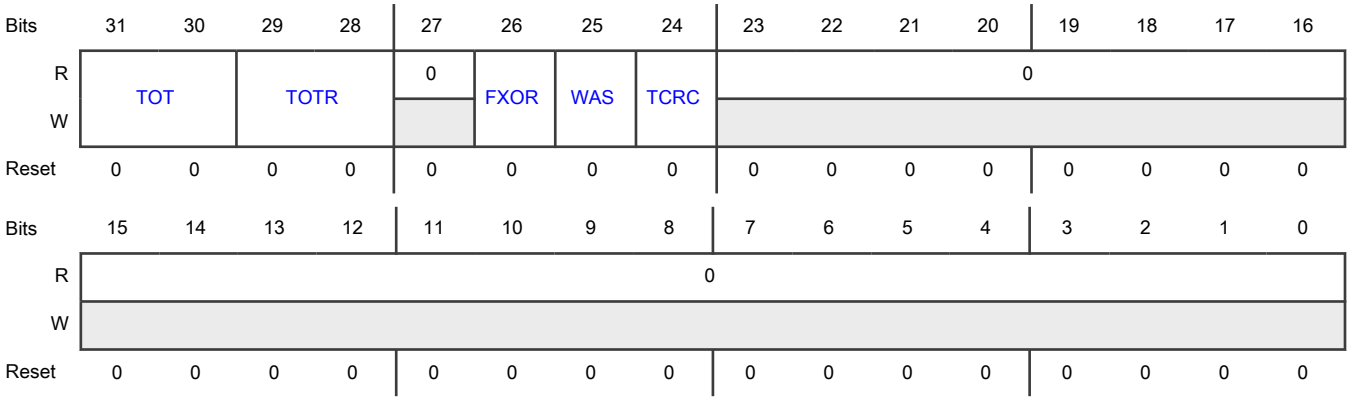
Offset

Register	Offset
CTRL	8h

Function

Sets control for CRC. You must write 1 to the appropriate fields of this register before starting a new CRC calculation, which you can initialize by writing 1 to CTRL[WAS] and then writing the seed into DATA.

Diagram



Fields

Field	Function
31-30 TOT	Transpose Type for Write Sets transpose type for the values written to DATA. See Transpose feature for the available transpose options. 00b - No transposition 01b - Bits in bytes are transposed, but bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed, no bits in a byte are transposed.
29-28 TOTR	Transpose Type for Read Sets transpose type for the values read from DATA . See Transpose feature for the available transpose options. 00b - No transposition 01b - Bits in bytes are transposed, but bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed, no bits in a byte are transposed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
27 —	Reserved
26 FXOR	Complement Read of CRC Data Register Enables on-the-fly complementing of read data. Some CRC protocols require the final checksum to be XORed with FFFFFFFFh or FFFFh. 0b - Disables XOR on reading data. 1b - Inverts or complements the read value of the CRC Data.
25 WAS	Write as Seed Specifies whether writes to DATA are data values or seed values. When this field = 1, the value that you write to is considered as seed value. When this field = 0, the value that you write to is considered as data for CRC calculation. 0b - Data values 1b - Seed values
24 TCRC	TCRC Defines the width of CRC. 0b - 16 bits 1b - 32 bits
23-0 —	Reserved

58.8 Glossary

Transpose	Flipping input or output data bits (or bytes)
Seed value	Initial value of CRC calculation

Chapter 59
Power Conversion and Motor Control (PCMC)

59.1 Introduction

The PCMC subsystem is a group of modules that can be interconnected to perform a variety of real-time tasks, such as:

- Motor control
- Power conversion
- Advanced PWM generation
- Lighting control

The modules that make up PCMC are:

- ADC
- BCTU
- eMIOS
- LCU
- LPCMP
- TRGMUX

See Feature comparison for the number of instances of each module in your chip.

59.2 Block diagram

The figure and table below show a typical configuration.

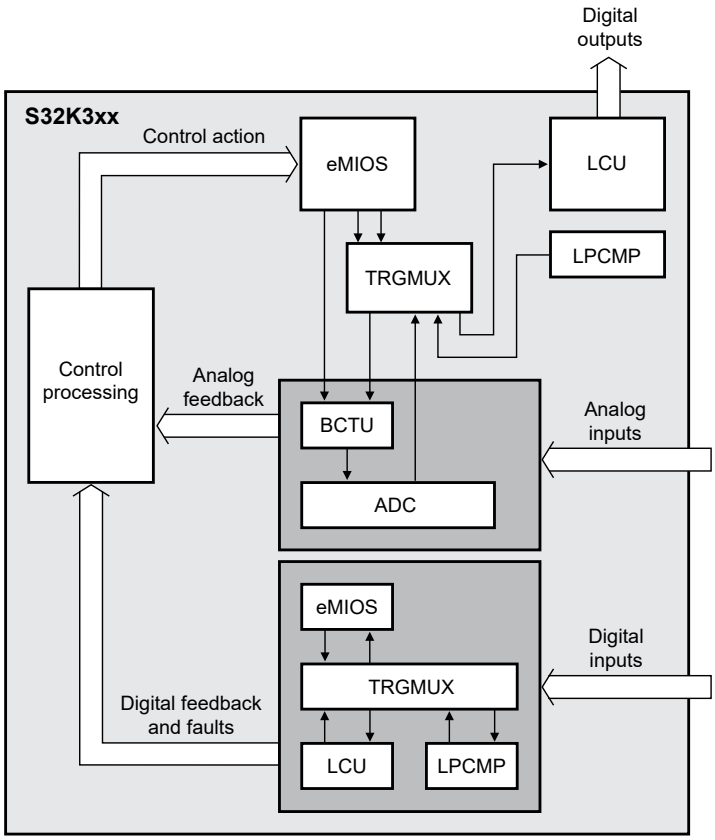


Figure 233. Block diagram

Table 330. Block diagram components

Component	Description
ADC	Measures external analog signals
BCTU	Performs advanced ADC triggering
Control processing	Arm Cortex-M7 core: • Processes digital and analog inputs to generate control outputs • Writes control outputs to peripherals
eMIOS	• Generates high-resolution PWM outputs • Measures time-based digital inputs
LCU	Performs programmable logic functions and fault control
LPCMP	Compares analog values to detect faults
TRGMUX	• Routes signals between internal peripherals • Routes external signals to internal peripherals

59.3 Functional overview

59.3.1 Analog signal measurement

ADC measures the voltage of external analog signals and converts that voltage to a digital value. Each ADC instance operates independently of other instances. Software or hardware can trigger conversions. Together with BCTU and eMIOS, ADC can preempt normal measurements by injecting high-priority measurements when needed.

See Analog-to-Digital Converter.

59.3.2 Advanced ADC triggering

BCTU works with ADC to initiate conversions triggered by outputs from other modules in the PCMC subsystem, such as PWM signals from eMIOS or LCU sequential logic outputs.

With BCTU, you can group measurements into configuration lists containing up to 32 items. Each item contains information such as:

- ADC instance to use for the conversion
- The ADC channel
- The trigger event for initiating the next conversion
- The conversion list address

BCTU can store conversion results by routing them through DMA or putting them in FIFO queues. The FIFO queues enable conversions to occur seamlessly by storing conversion results without software intervention.

BCTU has 72 trigger inputs, 69 of which come from the eMIOS channel outputs. The three remaining trigger inputs come from other on-chip modules via TRGMUX. You can also trigger conversions by software through the BCTU register interface.

BCTU can issue a single conversion or a list of conversions based on a single trigger occurrence. BCTU signals the eMIOS timers when ADC receives a single command or a list of commands. ADC sends conversion data back to BCTU, which loads it in the ADC*n* Result Data (ADC*n*DR) register for the CPU to read.

BCTU-to-ADC interface illustrates the connections between BCTU and an ADC.

59.3.3 BCTU-to-ADC interface

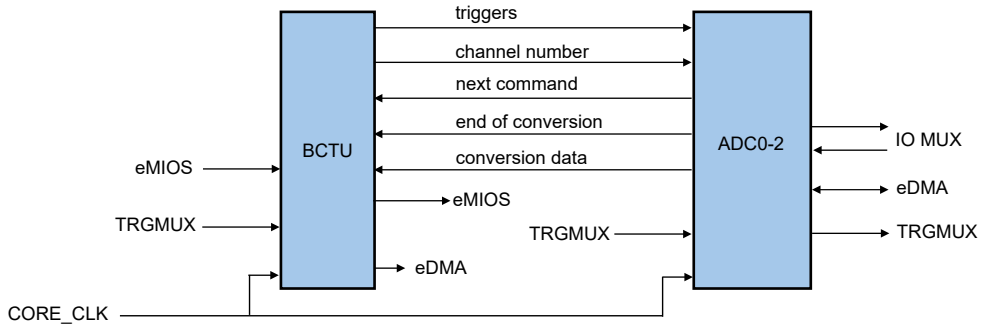

Figure 234. BCTU-to-ADC interface

59.3.4 Generate PWM outputs and measure digital inputs

eMIOS generates high-resolution PWM outputs. Each eMIOS instance has 23 dedicated channel outputs. You can configure each channel to operate in a different mode. Depending on the mode, eMIOS channels can:

- Measure the period of an input signal
- Measure the width of an input pulse
- Function as general-purpose I/O
- Count pulses or edges
- Capture input values
- Compare outputs

For example, eMIOS can generate periodic ADC triggers. Using TRGMUX, you can route eMIOS triggers to other on-chip peripherals such as LCU, another eMIOS instance, external chip I/O, and so on.

eMIOS connections illustrates the input and output connections for eMIOS.

- Enhanced Modular IO Subsystem (eMIOS)
- Body cross-triggering unit (BCTU)
- Trigger Mux (TRGMUX)

59.3.5 eMIOS connections

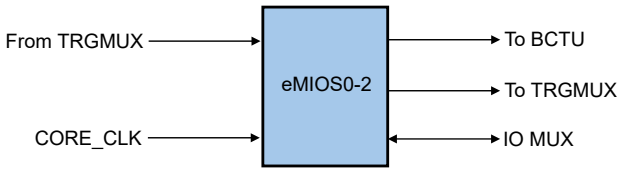

Figure 235. eMIOS connections

59.3.6 Create combinatorial and sequential logic functions

LCU enables you to implement hardware-based combinatorial and sequential logic on the chip. This capability reduces cost and decreases application size.

Each LCU instance has 12 dedicated inputs and 12 outputs. You can use LCU to implement a variety of combinatorial and sequential logic functions with no CPU intervention, including a simple OR gate, flip flops, and motor control logic. As detailed in Fault detection, LCU also plays a significant role in fault management.

LCU connections shows the input and output connections for LCU.

See also:

- TRGMUX connectivity file attached to this document

59.3.7 LCU connections

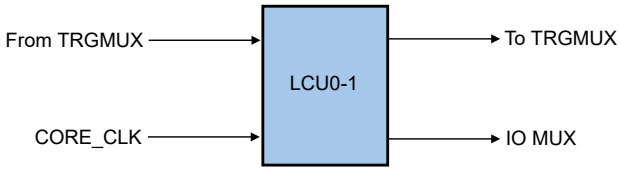

Figure 236. LCU connections

59.3.8 Fault detection

The PCMC subsystem uses LPCMP and LCU to implement fault detection.

LPCMP can detect fault conditions (such as short circuits, over-voltages, and excessive temperature) by comparing an external input voltage to a programmable reference voltage. It produces a digital output that indicates whether the input voltage is higher or lower than the reference voltage.

The chip can detect faults via external digital or analog signals. TRGMUX routes digital signals from SIUL to a peripheral to trigger the appropriate behavior.

LCU has four force inputs that you can use to manage fault assertion via its own internal logic mechanism.

The typical reaction to the presence of fault is to put the system in a safe state by:

- Deasserting output signals such as PWM outputs controlling a power stage.
- Disconnecting an entire circuit by switching off a relay.

See also Low Power Comparator (LPCMP).

59.3.9 Programmable module interconnections

TRGMUX enables you to interconnect on-chip peripherals to create application-specific configurations. TRGMUX has 128 inputs and 111 outputs, which you can interconnect in hundreds of combinations through software during runtime.

You can also route on-chip peripheral outputs to chip I/O pins to enable signal debugging. Similarly, you can route external signals to on-chip peripheral inputs.

NOTE

There is a two-cycle AIPS_SLOW_CLK delay through TRGMUX.

For details of PCMC interconnections, see PCMC connections diagram.

The attached TRGMUX connectivity file, a portion of which appears below, shows the interconnections possible between module instances. Column B in the spreadsheet lists TRGMUX inputs. Row 3 lists TRGMUX outputs. A connection between an input and an output is possible if the intersecting cell of the input row and the output column is blank. "NA" indicates that a connection is not possible.

															Output no.	0	1	2	4	5	6

59.4 Reset, clocking, and other considerations

59.4.1 Reset

ADC, BCTU, eMIOS, LCU, and TRGMUX fully reset during a POR, destructive reset, or functional reset.

See also:

- Module reset status
- Software reset

59.4.2 Clocking

Detailed clocking information is given in the links below. In summary:

- CORE_CLK clocks ADC, BCTU, eMIOS, and LCU.
- AIPS_SLOW_CLK clocks TRGMUX.
- In general, you must set AIPS_SLOW_CLK to one-fourth or one-half the frequency of CORE_CLK.

See also:

- ADC and motor control modules
- System clocking configurations
- System clock frequency limitations
- Clock frequency

59.4.3 Power modes

All ADC, BCTU, eMIOS, LCU, and TRGMUX instances operate only in Run mode. None of the instances operate in Standby mode.

See also:

- Module reset status
- ADC modes of operation
- LCU modes of operation

59.5 Use case examples

59.5.1 Motor control use case

The following sections show:

- A PMSM control system
- A BLDC control system

Both PMSM and BLDC use a rotating magnetic stator field to turn the stator consisting of permanent magnets. The stator is driven by 3-phase AC voltage. The difference between PMSM and BLDC is in how stator position is calculated.

- PMSM calculates stator position by measuring back EMF from the motor.
- BLDC calculates stator position based on feedback from motor sensors.

59.5.1.1 PMSM motor control use case

59.5.1.1.1 Generic PMSM motor control

The following figure and table illustrate a generic PMSM motor control system. The feedback loops in the system create a motor control loop.

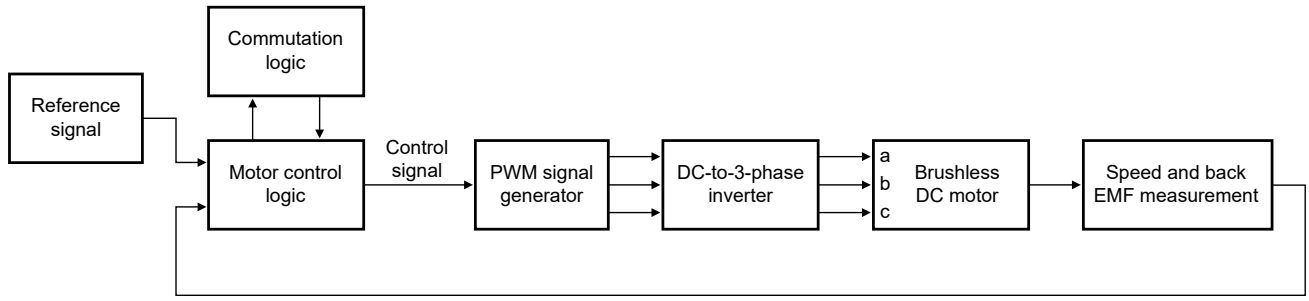

Figure 239. Generic PMSM motor control

Table 331. Block diagram components

Block	Description
Angular position sensor	Generates data that enables commutation logic to calculate rotor position.
Brushless DC motor	Electronically commutated electric motor.
Commutation logic	Compares values from the rotor angular position sensors to entries in a lookup table, and applies voltage to stator winding corresponding to same set of values in lookup table.

Table continues on the next page...

Table 331. Block diagram components (continued)

Block	Description
DC-to-3-phase inverter	Switching network that transmits power to the motor stator windings according to a control signal.
Motor control logic	• Compares speed measurement to required speed and adjusts the PWM signal generator. • Generates the assertions for the PWM signal generator according to commutation logic input.
PWM signal generator	Generates PWM signal voltage source.
Reference signal	Signal that indicates required motor speed.
Speed and back EMF measurement	An ADC is linked to a shunt resistor to perform measurements and detect over-current conditions. If one is found, then hardware generates a fault interrupt.

59.5.1.1.2 PMSM motor control

The PCMC subsystem consists of a group of modules that enable you to implement PMSM motor control loops in a variety of ways. The following figure and table illustrate one possible implementation.

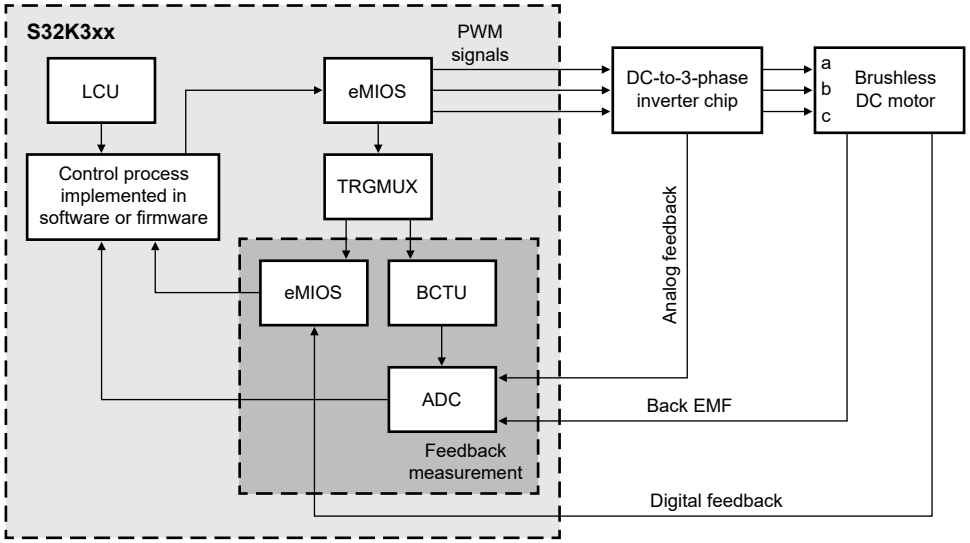

Figure 240. PMSM motor control

Table 332. Block diagram components

Block	Description
ADC	Measures analog inputs (currents and/or voltages) and converts to digital values. Typically, it measures currents and can be configured to generate a fault interrupt when a measured input is outside a pre-defined acceptable range.
BCTU	Triggers conversions by ADC.
Control process	Provides top-level system control functions for FOC or another feasible control algorithm:

Table continues on the next page...

Table 332. Block diagram components (continued)

Block	Description
	• Compares speed measurement to required speed and adjusts the PWM signal generator. • Generates the assertions for the PWM signal generator according to commutation logic input.
DC-to-3-phase inverter	Switching network that transmits power to the motor stator windings according to a control signal.
eMIOS	• Generates PWM input for DC to 3-phase inverter. • Measures digital feedback inputs—BLDC position sensors, for example.
LCU	Implements commutation lookup table. Control Process compares values from the angular position sensors to entries in the lookup table. It then applies voltage to stator winding corresponding to same set of values in lookup table.
TRGMUX	• Enables interconnect to the required set of on-chip peripherals. • Indirectly triggers ADC sampling via BCTU. • Triggers eMIOS to measure digital feedback signals.

59.5.1.2 Sensored BLDC motor control use case

59.5.1.2.1 Generic sensored BLDC motor control

The following figure and table illustrate a generic sensored BLDC motor control system. The feedback loops in the system create a motor control loop.

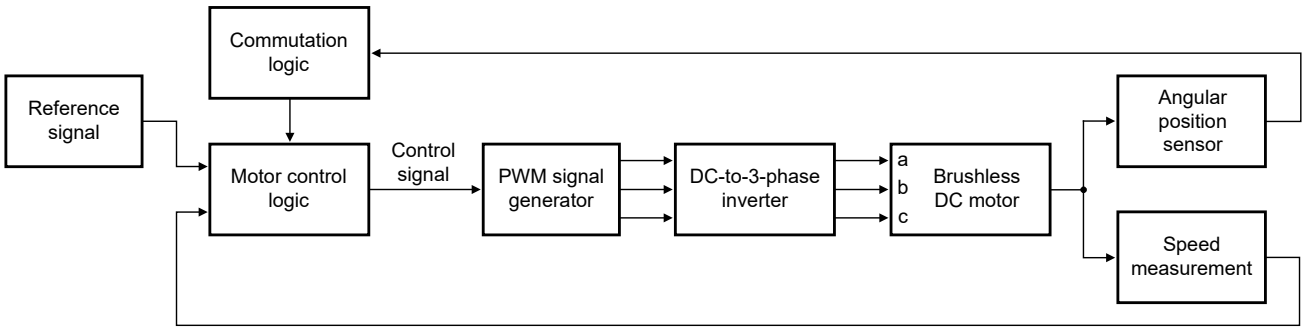

Figure 241. Generic sensored BLDC motor control

Table 333. Block diagram components

Block	Description
Angular position sensor	Hall effect sensors or optical decoders detect rotor position
Commutation logic	Compares values from the angular position sensors to entries in a lookup table and applies voltage to stator winding corresponding to same set of values in lookup table
Reference signal	Signal that indicates required motor speed

Table continues on the next page...

Table 333. Block diagram components (continued)

Block	Description
DC-to-3-phase inverter	Switching network that transmits power to the stator windings according to a control signal
Motor control logic	• Compares speed measurement to required speed and adjusts the PWM signal generator • Generates the assertions for the PWM signal generator according to commutation logic input
Speed measurement	Uses an ADC linked to a shunt resistor to perform measurements and detect over-current conditions, in which case hardware generates an interrupt.

59.5.1.2.2 PCMC sensored field-oriented control (FOC) of 3-phase BLDC motor

FOC is a VFD control method in which the stator currents of a 3-phase AC electric motor (such as BLDC, PMCM, reluctance motor, or other spinning electrical machine) is identified as a vector.

The PCMC subsystem consists of a group of modules that enable you to implement sensored FOC BLDC motor control loops in a variety of ways. The following figure and table show one possible implementation.

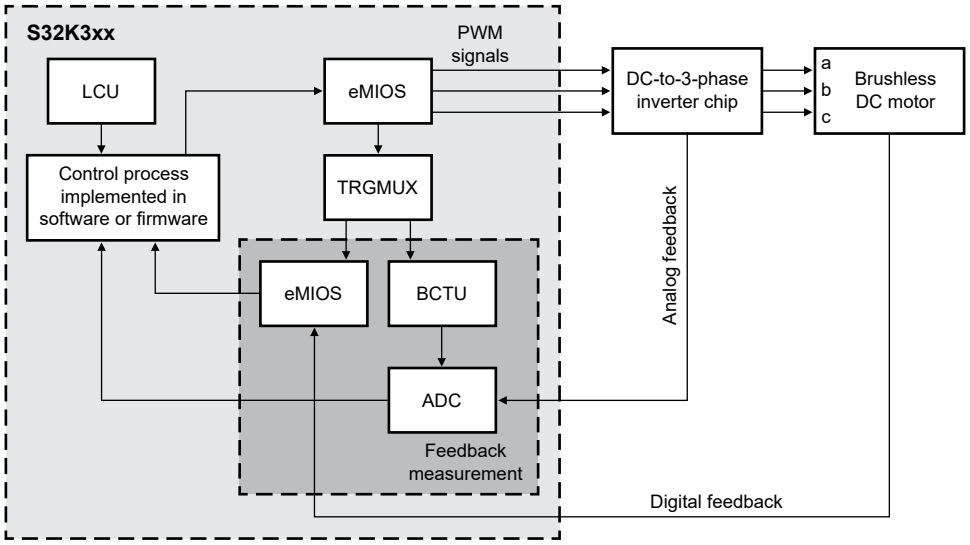

Figure 242. PCMC sensored BLDC motor control

Table 334. Block diagram components

Block	Description
ADC	Measures analog inputs (currents and/or voltages) and converts to digital values. Typically, it measures currents, and can be configured to generate a fault interrupt when a measured input is outside a pre-defined acceptable range.
BCTU	Triggers conversions by ADC.
Control process	Provides top-level system control functions for FOC control:

Table continues on the next page...

Table 334. Block diagram components (continued)

Block	Description
	• Compares speed measurement to required speed and adjusts the PWM signal generator. • Generates the assertions for the PWM signal generator according to commutation logic input.
DC-to-3-phase inverter	Switching network that transmits power to the motor stator windings according to a control signal.
eMIOS	• Generates PWM input for DC to 3-phase inverter. • Measures digital feedback inputs—BLDC position sensors, for example.
LCU	Implements commutation lookup table. Control process compares values from the angular position sensors to entries in the lookup table. It then applies voltage to stator winding corresponding to same set of values in lookup table.
TRGMUX	• Enables interconnect of the required set on on-chip peripherals. • Indirectly triggers ADC sampling via BCTU. • Triggers eMIOS to measure digital feedback signals.

59.6 Design considerations

59.6.1 ADC design considerations

The following topics discuss factors that affect ADC function in applications.

59.6.1.1 ADC measurement accuracy

The FOC motor control algorithm requires a high degree of confidence in the reliability of conversion data. Here are some best practices that contribute to ADC precision.

- Use precision channels (see ADC precision channels).
- Minimize input noise (see ADC input noise).
- Use BCTU triggering (see ADC triggering).

59.6.1.1.1 ADC precision channels

See the chip-specific ADC configuration information for the number of precision channels for each ADC instance.

See the channel mapping table for the channel numbers for the precision channels.

59.6.1.1.2 ADC input noise

Regardless of the application, ADCs are inherently sensitive to input noise. The following best practices help minimize input noise.

- Avoid simultaneous conversions.
- Consider using a low-pass filter on input pins.

All variants of this chip include multiple, independent ADC instances, so it is easily possible to have simultaneous sampling by different ADC instances. This should be avoided, though, because ADC sampling can cause noise on adjacent device ADC inputs. Avoidance of simultaneous sampling should be ensured by software design. This is important for implementations of the FOC algorithm.

Additionally, an RC low-pass filter on ADC input pins can help reduce noise and enhance accuracy.

59.6.1.1.3 ADC triggering

Some applications, including FOC motor control, must use BCTU for precise triggering of ADC measurement. This is because the FOC algorithm requires sampling at specific times to implement the “observer/predictor”. BCTU makes it possible to perform precisely-timed ADC measurement.

For less exigent algorithms or non-closed-loop controlled motors, BCTU triggering and precision ADC channels are not necessarily required.

59.6.1.2 Example ADC configurations

Following are some ADC configurations that might be used for FOC motor control.

Table 335. Example ADC configurations

Description	Settings
Single-shot mode	• Enable Overwrite (OWREN=1) • Disable Write Left-Aligned (WLSIDE=0) • Select single shot (MODE=0) • Disable External Trigger (TRGEN=0) • Disable Injection Trigger (JTRGEN=0) • Disable BCTU triggering (BCTUEN=0) • Disable averaging (AVGEN=0) • Select conversion clock = 1/2 module clock (ADCCLKSEL=01)
Normal conversion scan mode	• Enable Overwrite (OWREN=1) • Disable Write Left-Aligned (WLSIDE=0) • Select looped conversions (MODE=1) • Disable External Trigger (TRGEN=0) • Disable Injection Trigger (JTRGEN=0) • Disable BCTU triggering (BCTUEN=0) • Disable averaging (AVGEN=0) • Select conversion clock = 1/2 module clock (ADCCLKSEL=01)
BCTU control mode	• Enable Overwrite (OWREN=1) • Disable Write Left-Aligned (WLSIDE=0) • Select single shot (MODE=0) • Disable External Trigger (TRGEN=0) • Disable Injection Trigger (JTRGEN=0) • Enable BCTU triggering (BCTUEN=1) • Disable averaging (AVGEN=0) • Select conversion clock = 1/2 module clock (ADCCLKSEL=01)

Table continues on the next page...

Table 335. Example ADC configurations (continued)

Description	Settings
BCTU trigger mode	• Enable Overwrite (OWREN=1) • Disable Write Left-Aligned (WLSIDE=0) • Select single shot (MODE=0) • Disable External Trigger (TRGEN=0) • Disable Injection Trigger (JTRGEN=0) • Enable BCTU triggering (BCTUEN=1) • Enable all trigger sources (BCTU_MODE=1) • Disable averaging (AVGEN=0) • Select conversion clock = 1/2 module clock (ADCCLKSEL=01)

59.6.2 BCTU design considerations

For reasons discussed in ADC triggering, some applications require precise ADC triggering and BCTU provides that capability. The following topics discuss some design considerations when using BCTU.

59.6.2.1 BCTU or ADC data retrieval

Although the primary function of BCTU is to provide precisely timed triggers for ADC conversions, there is some overlap in BCTU and ADC function in that conversion data can be retrieved from either module. For applications in which frequent conversions are performed, such as real-time motor control, BCTU offers a distinct advantage over ADC, because BCTU trigger sources can be configured to route conversion results to a BCTU internal FIFO. Doing so prevents subsequent conversion data from overwriting previous data, making it available for either direct access or DMA transfer to system RAM.

59.6.2.2 Disabling BCTU triggers

There are fault scenarios in which an application must disable BCTU triggers as part of putting the system into a safe state. Examples include:

- Over-voltage condition
- Under-voltage condition
- Calibration parameter mismatch between the embedded motor control system and the motor

Application fault reaction design must include the disabling of BCTU triggers in scenarios in which either system conditions indicate an impending failure, or ADC conversion data is outside control boundaries.

59.6.3 eMIOS design considerations

In a BLDC motor control application, eMIOS plays a central role, providing the driving PWM signal as well as performing feedback signal measurements. The following topics discuss eMIOS considerations in the application design.

59.6.3.1 PWM considerations

In a BLDC motor control application, PWM/power signal requirements are affected by a number of parameters, including:

- Displacement Power Factor
- DF
- THD
- DVA

- CF
- FF

Ensure that the above parameters are included when choosing the timebase and prescaler combination for eMIOS channels producing PWM signals.

59.6.3.2 Input measurement

In a BLDC motor control application, eMIOS measures feedback signals for the motor and provides critical information to the control system. Selecting a timebase and prescaler for eMIOS channels performing input measurement tasks is usually a tradeoff between application requirements for precision and the computational cost in relation to the selected clock speed.

For example, some applications like electric steering demand an extremely precise control for position and torque. This is different from a compressor e-motor, where speed and torque do not demand rigid precision requirements.

Other considerations are related to control of:

- THD
- FF
- GM
- pf correction

The above considerations are significant from the perspective of the PWM reaction speed for the output signal for BLDC applications. These parameters must be considered in the design.

59.6.3.3 eMIOS channel modes useful in motor control

Table 336. eMIOS channel modes useful in motor control

Mode	Description	Use in motor control
MCB	Modulus Counter Buffered (Up/Down)	Time base • PWM frequency • Reload
IPWM	Input Pulse Width Measurement	Capture modes: • Speed measurement • Position measurement • Voltage (duty cycle)
IPM	Input Period Measurement	Speed measurement
PEC	Pulse Edge Counting	Position measurement
OPWMCB	Center aligned Output PWM Buffered with dead time	PWM duty cycle
OPWMB	Output Pulse Width Modulation Buffered	Trigger placement within the period
OPWMT	Output Pulse Width Modulation Trigger	Trigger placement within the period

59.6.3.3.1 MCB PWM and trigger generation

The following figure shows one option for PWM and trigger generation.

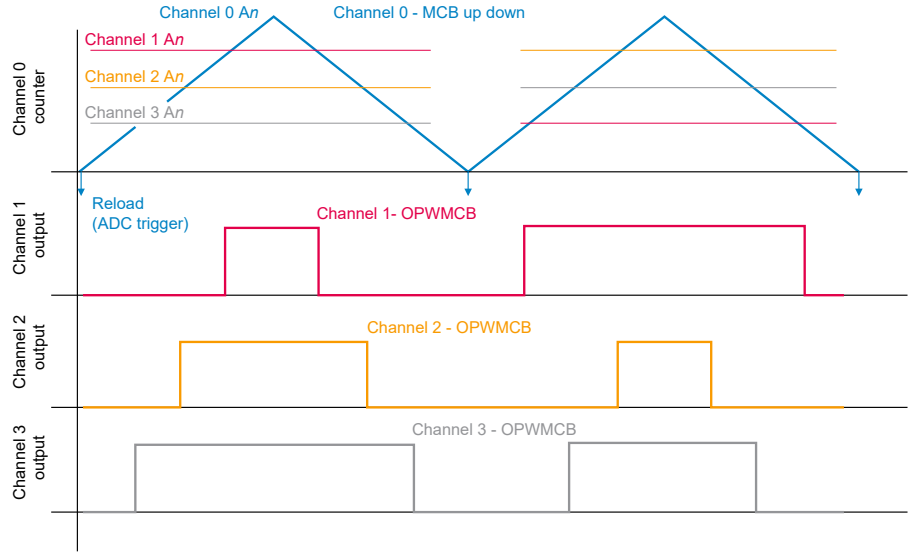

Figure 243. MCB PWM trigger generation

59.6.3.3.2 OPWMCB PWM and trigger generation

The following figure shows another option for PWM and trigger generation.

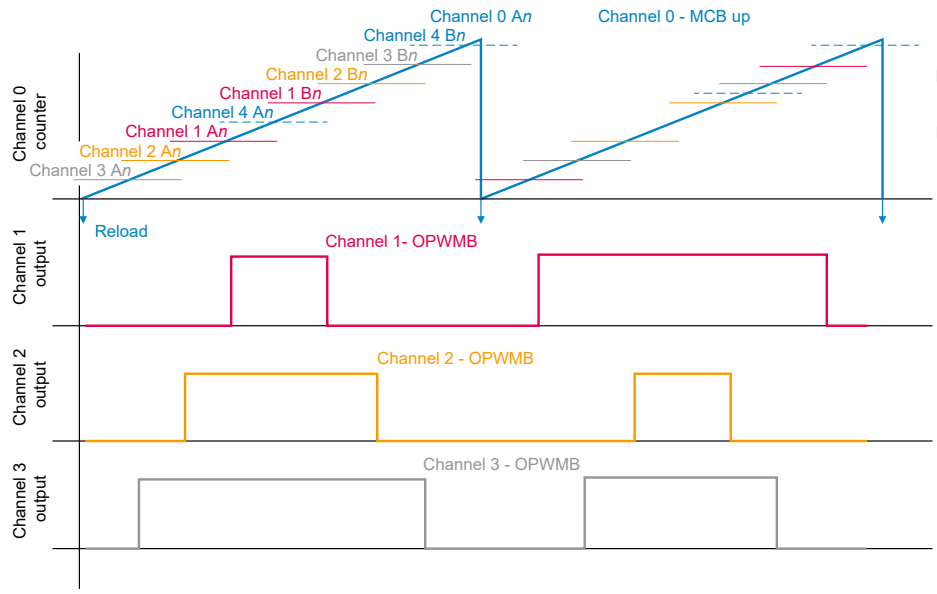

Figure 244. OPWMCB PWM trigger generation

59.7 Glossary

BLDC	Brushless DC. An electronically commutated DC motor.
CF	Crest Factor. A waveform parameter that is the ratio of peak values to its RMS value.
DF	Distortion Factor.

Displacement Power Factor	In power electronics, the phase relationship between voltage and current: $\cos(\theta_v - \theta_i)$, where θ_v is the phase of the voltage and θ_i is the phase of the current.
DVA	Distortion Volt-Amps.
FF	Form Factor.
FOC	Field-Oriented Control.
GM	Gain Margin.
pf	Power factor. In power electronics, it is the ratio of average power to RMS power.
PMSM	Permanent Magnet Synchronous Motor.
THD	Total Harmonic Distortion.
VFD	Variable-Frequency Drive.

Chapter 60
Analog-to-Digital Converter (ADC)

60.1 Chip-specific ADC information

60.1.1 ADC Configuration

This chip has up to 3 instances of ADC. ADC channels are divided into 3 groups - Precision, Standard and External (each with independent configuration settings and different accuracy/performance level). The following table shows the ADC configuration:

Table 337. ADC instances

Instance	S32K388/S32K389/S32K358/ S32K348/S32K338/S32K328/S32K344/ S32K324/S32K314	S32K342/S32K322/S32K341/S32K312/ S32K311/S32K310

1. Channels marked with “-“ means they are reserved and access to any reserved channel may result in inappropriate data.

NOTE

The decoding signals for the selection of external ADC channels (ADC_X) are gray-encoded.

NOTE

Value of ANAMUX_OUT is selected by DCMRWF1[SUPPLY_MON_SEL] field.

NOTE

The module clock mentioned in this chapter is CORE_CLK for this chip.

60.1.2 ANAMUX for internal supply monitoring

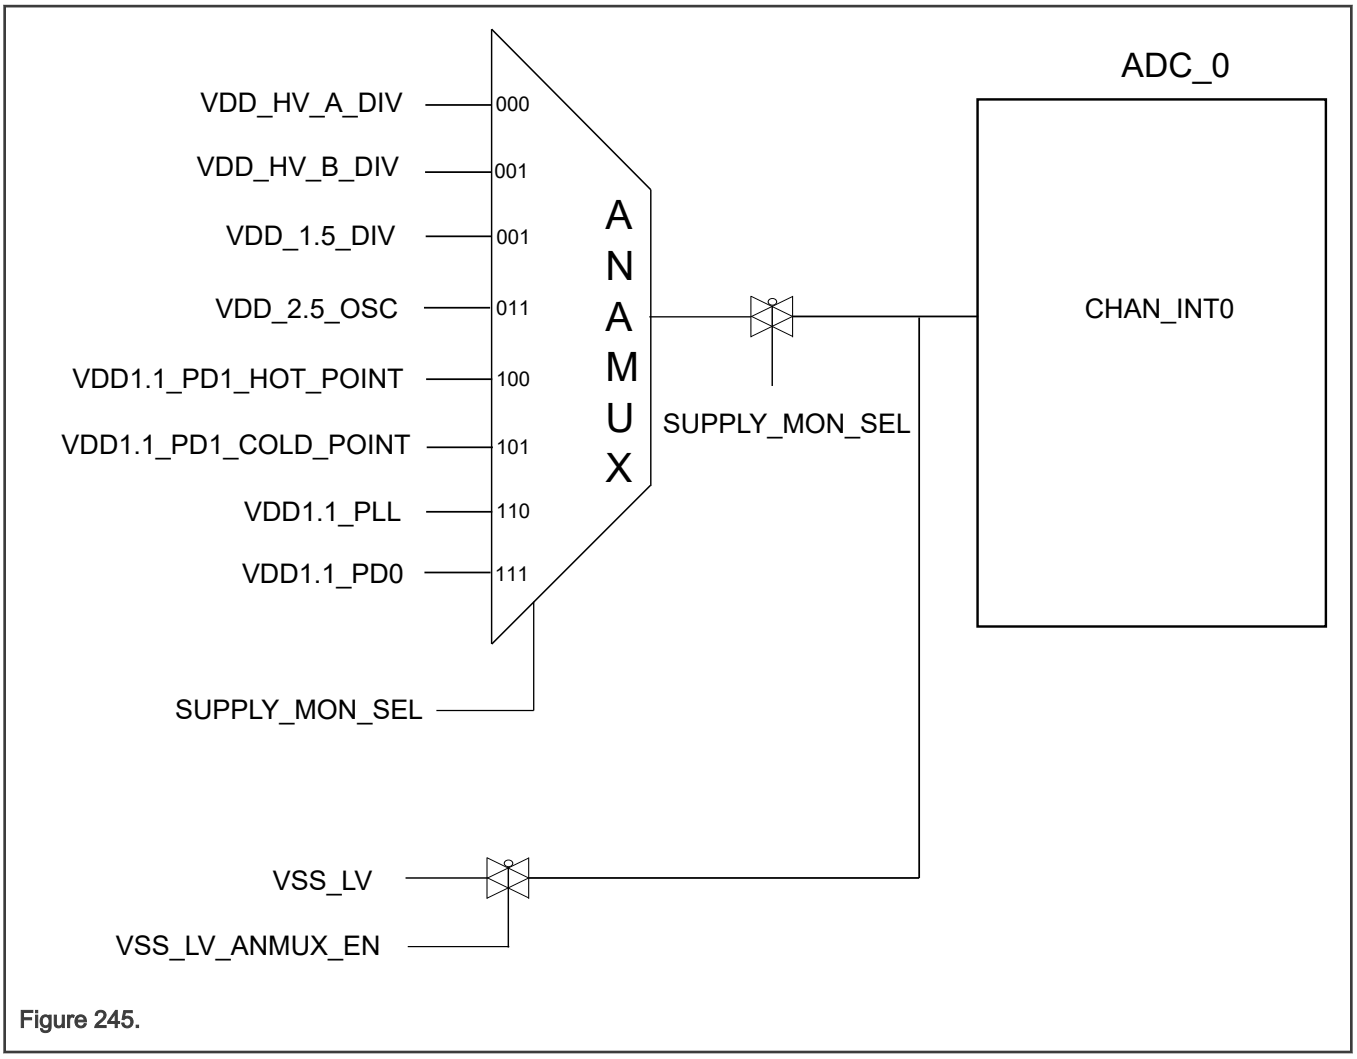

Figure 245.

NOTE

VDD_HV_B_DIV, VDD_1.5_DIV are not available in S32K312 and S32K311.

60.1.3 BCTU Interface

All 3 instances of ADC are triggered from the BCTU. The BCTU provides channel conversion commands to the ADC (includes channel number information). In addition, the ADC provides the conversion result back to the BCTU.

NOTE

Self-test conversion in BCTU mode is not supported in S32K3xx devices.

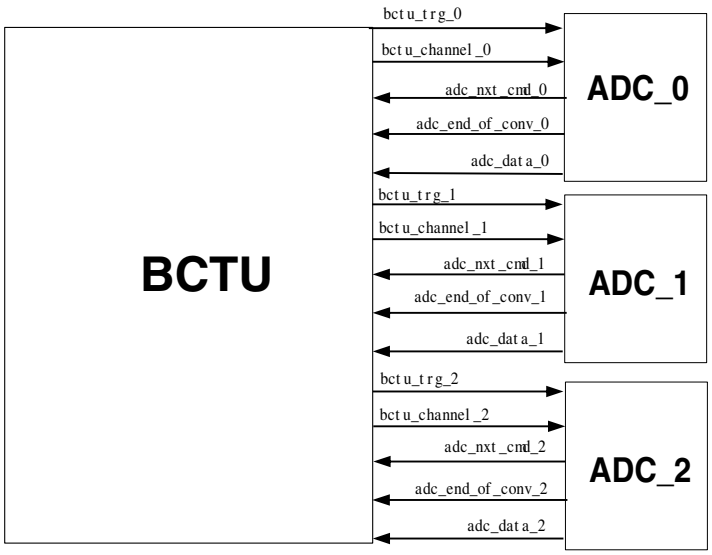

Figure 246. ADC Cross-triggering Unit

BCTU gives trigger pulse to all the 72 channels of ADC to initiate a conversion based on BCTU channel number.

BCTU-ADC result register

ADC result registers (ADCx_PCDRn[CDATA], ADCx_ICDRn[CDATA] and ADCx_ECDRn[CDATA]) store 15 bit conversion data. The BCTU ADC registers store 15-bit conversion data (BCTU_ADC0DR[ADC0_DATA], BCTU_ADC1DR[ADC1_DATA] and BCTU_ADC2DR[ADC2_DATA]).

60.1.4 DMA interface

Each ADC supports a single DMA request that can be requested after the conversion of every channel. The conversion result is stored into a register DMAR and is transferred via DMA or host access.

NOTE

The last ongoing conversion will be aborted as soon as ADC gets STOP request from the software and it will move to STOP mode.

60.1.5 Hardware triggers

In this chip, hardware trigger signals can be provided from TRGMUX outputs. This feature enables synchronous conversion of two independent ADC instances in parallel. If ADC is in Idle state (that is, no conversion phase ongoing and the MCR[PWDN] and MCR[ACKO] fields are 0) and the MCR[XSTRTEN] is set, an event on the external start signal causes ADC to start either normal or injected conversion operation. The MCR[NSTART]/MCR[JSTART] field is automatically set respectively. The normal conversion sync pulse is used with normal conversion trigger to synchronize the start timing of normal conversion between multiple ADC instances.

Table 341. Hardware triggers

TRGMUX output number	Hardware trigger functions
0	ADC_0 Normal Conversion
1	ADC_0 Injected Conversion
2	ADC_0 Normal Conversion Sync Pulse

Table continues on the next page...

Table 341. Hardware triggers (continued)

4	ADC_1 Normal Conversion
5	ADC_1 Injected Conversion
6	ADC_1 Normal Conversion Sync Pulse
8	ADC_2 Normal Conversion
9	ADC_2 Injected Conversion
10	ADC_2 Normal Conversion Sync Pulse

60.1.6 ADC Self-Test

It is important to check at regular intervals if the ADC is operating correctly. For this purpose a self test feature is provided. When self-test is enabled, the ADC automatically checks its components and flags errors.

60.1.7 ADC mux-mode channels

There are some channels in ADC which are driven by multiple pads. For this, GPR bits from DCM are used to define which pad is connected to a particular ADC channel.

For example as below, where ADC0 S8 is driven by GPIO_PAD0 (default) and GPIO_PAD45 (mux_mode). ADC2 S8 is driven by GPIO_PAD133 (default) and GPIO_PAD45 (mux_mode). ADC1 S8 has a dedicated pad GPIO45, so its TGATE doesn't need GPR bit gating. Similar implementation is for ADC0_S9 and ADC2_S9. Following DCM GPR bits have been used:

Table 342. ADC mux_mode GPR

ADC channel	GPR_bit	Connected pad
ADC0 Standard channel 8 (ADC0 S8)	DCM.DCMRWF4[1]	0: GPIO PAD0 (default) 1: GPIO PAD45
ADC0 Standard channel 9 (ADC0 S9)	DCM.DCMRWF4[2]	0: GPIO PAD1 (default) 1: GPIO PAD46
ADC 1 standard channel 14 (ADC1 S14)	DCM.DCMRWF4[3]	0: GPIO PAD69 (default) 1: GPIO PAD32
ADC 1 standard channel 15 (ADC1 S15)	DCM.DCMRWF4[4]	0: GPIO PAD4 (default) 1: GPIO PAD33
ADC1 Standard channel 22 (ADC1 S22)	DCM.DCMRWF4[5]	0: GPIO PAD124 (default) 1: GPIO PAD145
ADC1 Standard channel 23 (ADC1 S23)	DCM.DCMRWF4[6]	0: GPIO PAD125 (default) 1: GPIO PAD146
ADC2 Standard channel 8 (ADC2 S8)	DCM.DCMRWF4[9]	0: GPIO PAD133 (default) 1: GPIO PAD45
ADC2 Standard channel 9 (ADC2 S9)	DCM.DCMRWF4[10]	0: GPIO PAD132 (default) 1: GPIO PAD46

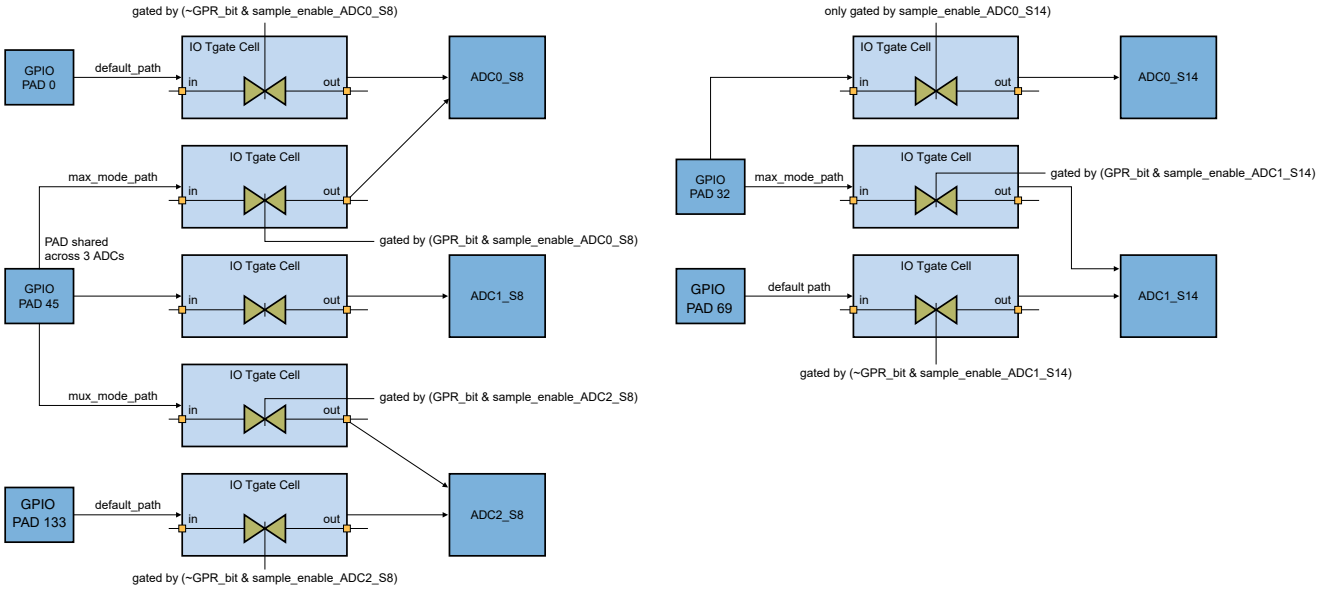

Figure 247. ADC channel interleaving

60.2 Overview

ADC produces a digital value from an input analog voltage using the SAR algorithm. It features various methods to trigger a conversion and offers flexibility in the selection of input channels. ADC is useful for a wide range of applications.

A configurable self-test capability supports use cases with increased requirements for functional safety.

60.2.1 Block diagram

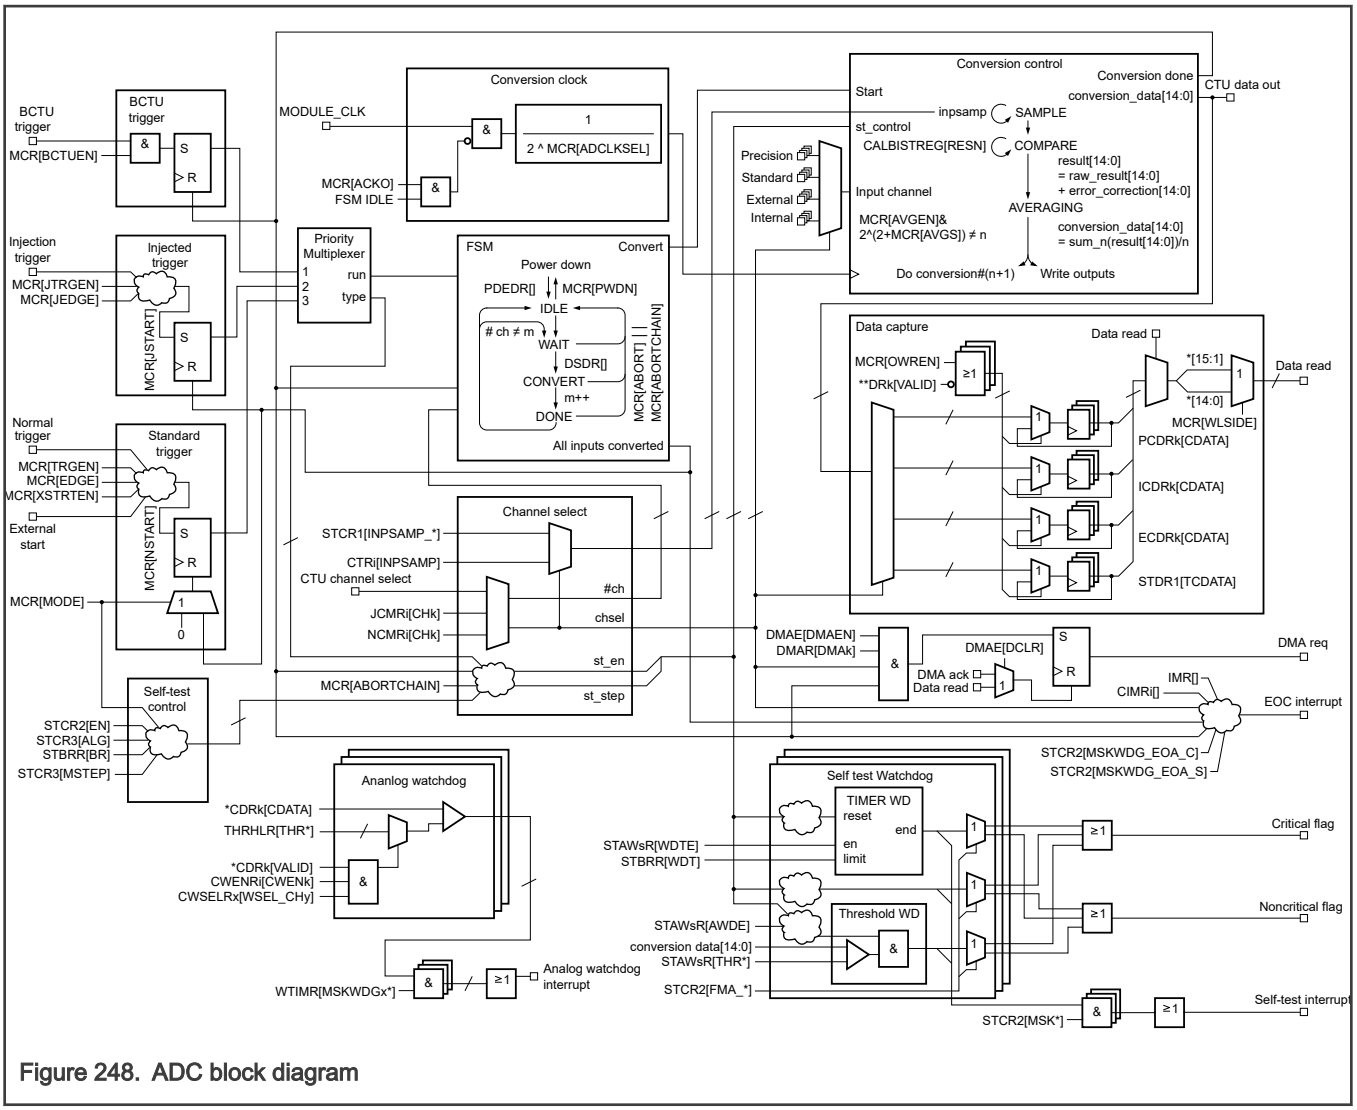

Figure 248. ADC block diagram

Guide to the diagram:

- The signal flow through the diagram is from left to right: inputs to blocks are on the left side, outputs are on the right.
- Block names have the first letters in uppercase and the other letters in lowercase—"Conversion Control," for example).
- Register names are in uppercase followed by a field name in brackets ("MCR[NSTART]," for example). Letters in lowercase are indexes. Asterisks are placeholders for letters (wildcards). Register names in the block diagram map to the names in ADC register descriptions.
- Signal names are in lowercase ("conversion done," for example).
- All digital signals shown are synchronous signals. Asynchronous inputs to the ADC are internally synchronized (synchronizers not shown).

The block diagram shows the signal flow through ADC from the left to the right and from the top to the bottom:

1. When ADC receives one of the three different types of triggers (BCTU, injected, or normal), the priority multiplexer initiates the conversion.
2. The input to be converted is selected in the Channel Select subblock, based on the type of trigger and on the self-test configuration.

3. The state machine (FSM) transitions from Idle state to Convert state. In case the channel to convert changed since the last conversion and this new channel is an external channel, the conversion starts after a delay configured by DSDR[DSD].
4. After a conversion begins, the Conversion Control block holds the internal capacitance network CDAC in the sample phase for a time defined by CTRi[INPSAMP].
5. During the compare phase, CALBISTREG[RESN] defines the number of steps used to execute the successive approximation algorithm. The error_correction values, determined during calibration, are added to the raw result. If averaging is enabled (MCR[AVGEN] = 1), up to 32 (specified via MCR[AVGS]) conversion results are averaged to obtain the result.
6. When the conversion completes and all averaging steps have completed:
    a. The conversion done signal indicates completion.
    b. Conversion_data[14:0] is written to the result registers in the Data Capture subblock.
    c. The FSM transitions into Done state.
7. The next input in the Channel Select block is selected and the next conversion is started by the transition of the FSM to Convert state. This continues until all selected inputs have been converted.
8. If an analog watchdog is enabled, the conversion result is compared to the configured threshold. If the limits are exceeded, an interrupt can be triggered.
9. Self-test can check the integrity of ADC, either interleaved with normal conversions or as a standalone check.
10. If an ongoing conversion is aborted (by writing 1 to MCR[ABORT]) or an ongoing conversion of a set of input channels is aborted (by writing 1 to MCR[ABORTCHAIN]), the FSM transitions into Idle state. The Conversion Control block stops the current conversion if MCR[ABORT] was written with 1, or finishes the current conversion if MCR[ABORTCHAIN] was written with 1. In both cases, the conversion done output signal of the Conversion Control block is set to 1.

Some details are not shown in the block diagram:

- Calibration must be performed to determine the error_correction values (see Calibration) before ADC can do meaningful conversions.
- An input can presample the internal low or high reference voltages to avoid a memory effect that may be present in the comparison due to a previous conversion (see Presampling).
- Monitor ADC status via status flags.
    - See Main Status (MSR) for the FSM state.
    - See Interrupt Status (ISR) to monitor interrupts.
    - See Channel End Of Conversion Flag For Precision Inputs (CEOCFR0) for conversion phase per input.
    - See the following registers to monitor analog watchdogs:
        - Analog Watchdog Out Of Range For Precision Inputs (AWORR0)
        - Analog Watchdog Out Of Range For Standard Inputs (AWORR1)
        - Analog Watchdog Out Of Range For External Inputs (AWORR2)

      See Analog Watchdog Threshold Interrupt Status (WTISR) to monitor analog watchdog interrupts.
    - See Self-Test Status 1 (STSR1) – Self-Test Status 4 (STSR4) to monitor self-test.

60.2.2 Features

- Selectable resolution (8-, 10-, 12-, 14-bit). Note that the conversion result is always 15 bits wide, even though the selected resolution is smaller (see CALBISTREG[RESN])
- Conversion data captured in a separate register for each input channel.
- Option to improve accuracy via averaging, which calculates conversion data by averaging the data of up to 32 conversions.

- Conversion triggers:
  - Normal conversion trigger converts a number of input channels, either once per trigger or continuously.
  - Injected conversion trigger interrupts an ongoing normal conversion and converts another set of input channels.
  - BCTU conversion trigger interrupts an ongoing conversion and converts an input channel, in which the input is selected and the conversion is started via the BCTU.
- An analog watchdog optionally monitors conversion data for each input channel and issues an interrupt if the converted data is below or above configurable limits.
- DMA functionality transfers conversion data to other modules.
- Programmable interrupts optionally issue an interrupt when conversion of one or of a set of input channels is finished.
- Self-test functions validate ADC structural integrity during functional operation and generate events with different severities on any finding.
- Conversion clock (AD_clk) control enables the use of ADC in systems with a higher clock frequency by using internal clock dividers.
- Auto turn-off of the conversion clock when ADC is idle.

60.3 Functional description

60.3.1 Clock

ADC is controlled by one clock signal, the module clock. Internally, the conversion circuit is controlled by the conversion clock, which is derived from the module clock.

The frequency of the conversion clock has to be within the limits defined in the data sheet. If the module clock frequency is higher than the maximum frequency of the conversion clock allowed during the functional conversion or during the calibration (see the chip data sheet), then you must configure the ADC conversion clock divider (MCR[ADCLKSEL]) so that the frequency of the conversion clock is within allowed limits. See Table 343.

Table 343. Clock configuration for highest conversion speeds

Module Clock Frequency f_mc[1]	Configuration during calibration	Configuration during functional conversion
40 MHz < f_mc ≤ 80 MHz	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 0h AMSIO[CMPCTRL0] = 0b	MCR[ADCLKSEL] = 0h AMSIO[HSEN] = 0h AMSIO[CMPCTRL0] = 0b
80 MHz < f_mc ≤ 120 MHz	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 1h AMSIO[CMPCTRL0] = 1b	MCR[ADCLKSEL] = 0h AMSIO[HSEN] = 1h AMSIO[CMPCTRL0] = 1b
120 MHz < f_mc ≤ 160 MHz	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 0h AMSIO[CMPCTRL0] = 0b	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 0h AMSIO[CMPCTRL0] = 0b
160 MHz < f_mc ≤ 240 MHz	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 1h AMSIO[CMPCTRL0] = 1b	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 1h AMSIO[CMPCTRL0] = 1b

Table continues on the next page...

Table 343. Clock configuration for highest conversion speeds (continued)

Module Clock Frequency f_mc[1]	Configuration during calibration	Configuration during functional conversion
240 MHz < f_mc ≤ 320 MHz	MCR[ADCLKSEL] = 3h AMSIO[HSEN] = 0h AMSIO[CMPCTRL0] = 0b	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 0h AMSIO[CMPCTRL0] = 0b
320 MHz < f_mc ≤ 480 MHz	MCR[ADCLKSEL] = 3h AMSIO[HSEN] = 1h AMSIO[CMPCTRL0] = 1b	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 1h AMSIO[CMPCTRL0] = 1b

1. Lower resulting frequencies are allowed—see the chip data sheet.

When ADC is not converting (state machine is in Idle state), the conversion clock can be turned off (MCR[ACKO]).

60.3.2 Modes of operation

ADC is always in Functional mode. No other mode selection exists.

- Put ADC into Power Down state by writing 1 to MCR[PWDN] to reduce power consumption.
- Gate the clock signal by writing 1 to MCR[ACKO] when ADC is in Idle state.

60.3.3 Conversion

ADC measures the voltage of a signal—it converts an analog input value into a digital representation. When you read the conversion result, you must divide this conversion result by the number of codes (defined by selected conversion resolution in CALBISTREG[RESN]), and multiply it with the reference voltage value. This calculation provides the voltage value of the converted signal.

To convert an analog input voltage into its digital representation, ADC:

1. Receives a signal, referred to as a trigger, indicating it is to perform a conversion.
2. Captures the voltage of a signal via internal capacitances in a process referred to as sampling.
3. Compares the voltage to the reference voltage, using the SAR algorithm.

Before a conversion can be performed, you must select:

- The trigger source(s) to use (on the chip level)
- The input channel(s) to convert (NCMR0–2, JCMR0–2)

Additionally, you can tailor the conversion to meet your needs by changing the default configuration. For example, you can:

- Configure ADC to convert the selected input channel(s) only once or continuously in a loop (MCR[MODE]).
- Specify the duration that ADC samples the input signal (CTR0/1/2).
- Specify the resolution of the conversion result by selecting the number of bits (CALBISTREG[RESN]).
- Enable an analog watchdog to generate an interrupt when a conversion result falls outside a specified range (see Analog watchdog functions).
- Enable the DMA interface to send requests and receive acknowledgments (see DMA functionality).
- Check the operational integrity of ADC by running a self-test (see Self-test).

After power-up or a functional reset, ADC remains in Power Down state until enabled by writing 0 to MCR[PWDN]. After the system is powered on, you must run the calibration (see Calibration), before you can do a meaningful conversion with ADC.

Some configuration fields (listed below) are writeable only in Power Down state. If you intend to write to them, you must do so before exiting Power Down state.

- Select the conversion clock frequency to be within the allowed limits for a conversion.

60.3.4 Normal trigger

Select the input channels to convert by configuring the fields in NCMR0, NCMR1, and NCMR2.

These registers must be programmed before the start of conversion. You cannot reconfigure them until the conversion of all selected channels is complete. The sequence is always to convert the selected input channels in this order:

1. Start from the lowest input channel of the precision input channels.
2. Proceed through the standard input channels in ascending order.
3. End with the highest input channel of the external input channels.

60.3.4.1 Starting conversions in normal conversion mode

After programming the required fields of the following registers, you can start a conversion by writing 1 to MCR[NSTART]:

- Normal Conversion Enable For Precision Inputs (NCMR0)
- Normal Conversion Enable For Standard Inputs (NCMR1)
- Normal Conversion Enable For External Inputs (NCMR2)
- Main Configuration (MCR)

A hardware trigger can also start a normal conversion.

- If the external trigger is enabled (MCR[TRGEN] = 1), an external trigger enable is detected to start the conversion. The enable is checked only during start of conversion.
- Detection of an active edge defined by MCR[EDGE] (rising = 1, falling = 0) on an external trigger transitions MCR[NSTART] to 1 and starts the normal conversion.
- When MCR[TRGEN] = 1 (for example, when external trigger is enabled), conversion can be started by software.
- Any external trigger or software initiated conversion in normal conversion mode is ignored during any ongoing conversion chain.

NOTE

To have reliable operation there must be a gap of 3 clock cycles between configuration of NCMRx and the start of a conversion (by writing 1 to MCR[NSTART], or arrival of an external or internal hardware start trigger). ADC calculates the number of channels to be converted during this period.

60.3.4.2 Operation modes in normal conversions

Two operational modes are available during normal conversion:

- One-Shot mode
- Scan mode

For normal conversion, select the mode via MCR[MODE]. The first phase of the conversion process involves sampling the analog channel. The next phase is the conversion phase, curing which the sampled analog value is converted to digital as shown in the following figure.

Figure 249. Normal conversion flow

In One-Shot mode (MCR[MODE] = 0), a sequential conversion specified in the NCMR*n* mask registers is performed only once. At the end of each conversion, the digital result of the conversion is stored in the corresponding data register (CDR*n*).

For example: Channels A→B→C→D→E→F→G→H are present in a device where channels B→D→E are to be converted in One-Shot mode. Conversion begins with channel B, followed by conversion of channels D and E. At the end of conversion of channel E, the scanning of channels stops.

MSR[NSTART] automatically transitions to 1 when a normal conversion starts. At the same time, MCR[NSTART] is reset to zero by hardware, enabling software to program a new start of conversion in advance. In this case, the new requested conversion starts after completion of the running/current conversion. However, for correct functioning of the device, you should program MCR[NSTART] for the new conversion only after completion of the current conversion. The application can wait for an ECH interrupt prior to writing 1 to MCR[NSTART] again.

If an external trigger starts the conversion chain, ADC does not observe the trigger input until the conversion chain is finished. After the chain is finished, the next chain can be triggered by another hardware trigger edge.

In Scan mode operation (MCR[MODE]=1), a sequential conversion of N channels specified in the NCMR*n* registers is continuously performed. At the end of each conversion, the result is stored in the corresponding data register, as in One-Shot mode.

MSR[NSTART] automatically transitions to 1 when a normal conversion starts. Unlike One-Shot mode, MCR[NSTART] is not reset to 0 in Scan mode. It can be reset by software when you must exit Scan mode. In that case, ADC completes the current chain and after the last conversion, it resets MCR[NSTART] to 0.

For example: Channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in Scan mode. MCR[MODE] = 1 selects Scan mode operation. Conversion starts from channel B followed by conversion of channels D→E. After conversion of channel E, the scanning of channel B starts followed by conversion of the channels D→E. This sequence repeats itself until MCR[NSTART] is reset to 0 by software.

If an external trigger starts a conversion, then MCR[NSTART] does not transition to 1. This scan chain can be stopped by writing 0 to MCR[NSTART]. The conversion stops when the ongoing chain is finished. Consequently, after it starts, the only way to stop Scan mode conversion is to write 0 to MCR[MODE].

End of conversion

In both modes, at the end of each conversion, an End of Conversion (EOC) interrupt is issued if enabled by the corresponding mask fields in CIMR*n* and IMR).

After conversion of all selected channels in NCMR*n* is complete, the conversion operation is considered finished. Then ISR[ECH] transitions to 1 and the End of Chain (ECH) interrupt is issued (if enabled in IMR[MSKECH]).

The corresponding channel field in the CEOCFR*n* register(s) is updated to indicate that data is available on data register CDR*n* of the respective channel.

If there is no channel selected in NCMR*n* and there is a start-of-conversion trigger, then ISR[ECH] is set to 1 and the End of Chain (ECH) interrupt is immediately issued (if enabled).

60.3.5 Injected trigger

An injected trigger enables you to convert a set of input channels although the standard trigger has already started conversion of another set of input channels. Each channel can be individually enabled by writing 1 to the corresponding field in JCMR0, JCMR1, or JCMR2.

The set of input channels of the injected trigger is converted only once. A continuous conversion of a set of input channels in a loop is only possible when started by a standard trigger. When an injected trigger is received, an ongoing conversion started by a standard trigger is interrupted. After the set of input channels of the injected trigger is converted once, the interrupted conversion of the set of input channels of the standard trigger resumes from the input channel that was interrupted, as shown in the following figure.

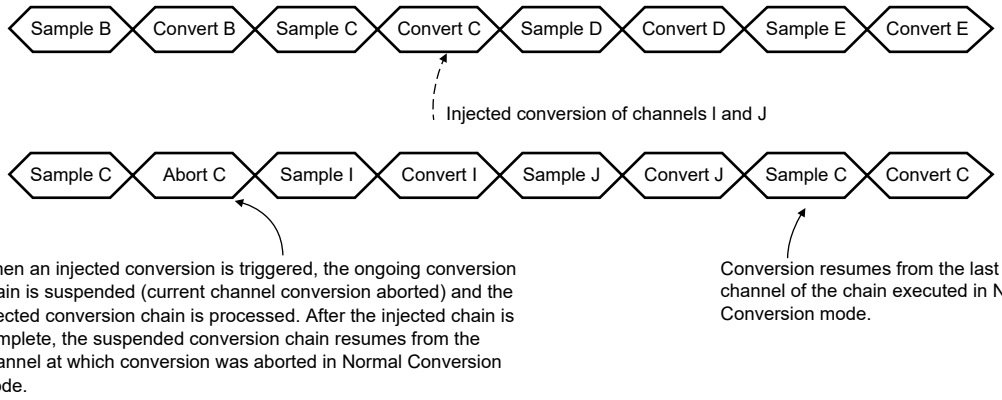

Figure 250. Injected trigger conversion sequence

60.3.5.1 Starting conversions in injected conversion mode

An injected conversion chain can be started:

- By software: When external triggering is disabled (MCR[JTRGEN] = 0), you can write 1 to MCR[JSTART], which causes the current conversion chain processed in Normal Conversion mode to be suspended and the injected chain to be processed.
- By external trigger: When external triggering is enabled (MCR[JTRGEN] = 1), a programmed event (rising/falling edge depending on the value of MCR[JEDGE]) on the injection external input starts the injected conversion.

MCR[JSTART] automatically transitions to 1 when the injected conversion chain starts. At the same time MCR[JSTART] is reset to 0, enabling software to program a new start of conversion in advance. In that case the new requested conversion starts after the running conversion completes.

At the end of each conversion, an End Of Injected Conversion (JEOC) interrupt is issued, if enabled by the corresponding mask field in Interrupt Mask (IMR). At the end of a chain, an End Of Injected Chain (JECH) interrupt is issued, if enabled by the corresponding mask field. Additionally, ADC writes 1 to ISR[JECH].

NOTE

If the content of all the Injected Conversion mask registers (JCMR*n*) is zero, that is, no channel is selected, the JECH interrupt is immediately issued after the start of conversion.

To have reliable ADC operation, there must be a gap of 3 cycles between configuration of JCMRx and starting of conversion (writing 1 to MCR[JSTART] or arrival of either an external or internal hardware start trigger). ADC calculates the total channel numbers to be converted during this period.

The corresponding channel bit in the CEOCFR*n* register is updated to indicate data is available in the channel's conversion data register, CDR*n*.

After starting, an injected chain conversion cannot be interrupted.

60.3.6 BCTU interface

The BCTU interface enhances ADC's injected conversion capability. It contains control inputs to select the channels to be converted from the appropriate event configuration register. Figure 251 shows the interface.

The BCTU generates a trigger (bctu_trigger) and a channel number (bctu_numchannel) to be converted. A single channel is converted for each request. After performing the conversion, ADC returns the result on the bctu_dataout bus together with two output signals named bctu_nextcmd and bctu_push. The assertion of signal bctu_nextcmd means ADC is ready to accept the next trigger from BCTU. The bctu_push signal is asserted at the end of conversion, meaning that conversion is finished and the conversion result available at output bctu_dataout is valid.

The conversion result is also saved in the corresponding channel's data register and is compared with analog watchdog thresholds if requested.

The signals bctu_trigger, bctu_nextcmd and bctu_push are all of type single-cycle active-high-pulse in the ADC clock domain. The channel number provided from BCTU must be valid when bctu trigger is active-high. The result data from ADC is valid with bctu_push high.

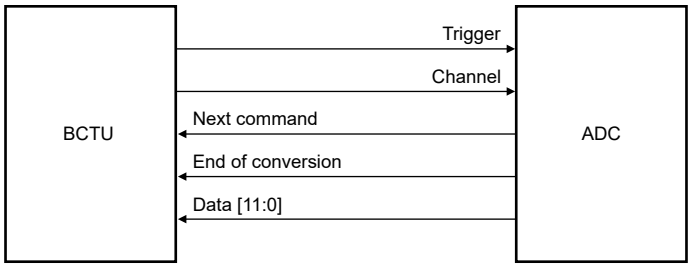

Figure 251. BCTU interface

The BCTU interface has two modes of operation:

- Trigger
- Control

To enable the BCTU interface, write 1 to MCR[BCTUEN]. The operating mode (Trigger or Control) can be fixed or programmable.

60.3.6.1 BCTU Trigger mode

In Trigger mode, normal and injected conversions can also be performed. All types of conversions can be initiated in this mode. The priorities among the three types of conversions are discussed below.

When a trigger is received, the channel number is taken as an injected channel value and the triggered injected conversion starts. MSR[BCTUSTART] transitions to 1 automatically at this point and it is also automatically reset to 0 when the triggered injected conversion is completed.

BCTU conversions must be requested only after successful ADC calibration. The application must prevent any BCTU trigger during calibration.

If a BCTU trigger is received during an ongoing injected conversion, the injected chain is aborted immediately and only the BCTU-triggered injected conversion proceeds. Additionally, MSR[JSTART] is reset to zero. The abort of an injected conversion is indicated by MSR[JABORT].

If a BCTU trigger is received during an ongoing normal conversion, the ongoing normal channel conversion is suspended and the BCTU-triggered injected conversion is processed. Normal conversion resumes from the suspended channel after completion of the BCTU-triggered conversion.

If a normal conversion is requested during BCTU conversion (MSR[BCTUSTART] = 1), the normal conversion starts after the BCTU conversion completes (MSR[BCTUSTART] is reset to zero).

Any injected conversion is discarded if requested during BCTU conversion and MCR[JSTART] is immediately reset to zero.

60.3.6.2 BCTU Control mode

In BCTU control mode (MCR[BCTU_MODE] = 0), only the BCTU can start a conversion. All other trigger sources are ignored.

Along with BCTU trigger, the information provided with signal bctu_numchannel is taken as the channel number for injected channel and BCTU triggered conversion starts. MSR[BCTUSTART] transitions to 1 automatically at the start of the conversion and it remains 1 unless BCTU is disabled by writing 0 to MCR[BCTUEN].

The conversion must be requested (generating bctu_trigger) when calibration has finished successfully. If a BCTU trigger is received during calibration execution, calibration is stopped immediately in order to satisfy the BCTU request. Calibration fails in this case.

60.3.7 Aborting a conversion

Two abort functions are provided:

- Abort of a single channel
- Abort of a chain

To abort an ongoing conversion, write 1 to MCR[ABORT]. The current conversion aborts and conversion of the next channel of the chain begins immediately.

Depending on the current state of a conversion, an Abort action may take 1 to 4 cycles of the bus clock. At the start of any conversion, and at the end of a particular conversion when internal state counters are changing, an abort action is delayed by a maximum of 3 cycles to put all states in a stable condition.

To ensure that the abort action completes, do not change MCR[ABORT] for the next 3 cycles.

Avoid writing 1 to MCR[ABORT] along with, and within 3 cycles of, writing 1 to MCR[NSTART] or MCR[JSTART].

During an abort:

- MCR[NSTART] and MCR[JSTART] remain 1, if not in the last channel of the chain.
- MCR[ABORT] is reset to 0 when the channel is aborted.
- The EOC interrupt corresponding to the aborted channel is not generated. This behavior applies to normal and injected conversions. If the last channel of a chain is aborted, the end of chain is reported by generating an ECH interrupt.

It is possible to abort the current chain of conversions by writing 1 to MCR[ABORTCHAIN]. In this case, the behavior of ADC depends on the value of MCR[MODE] (One-Shot/Scan operation modes). If Scan operation mode is disabled, MCR[NSTART] is automatically reset to 0 along with MCR[ABORTCHAIN]. Otherwise, in Scan Operation mode, a new chain is started. The EOC interrupt of the current aborted conversion is not generated but an ECH interrupt is generated to signal the end of the chain.

NOTE

For a single channel chain, an ECH interrupt is not generated for an abort or abort chain.

When an abort chain is requested while an injected chain is running over a suspended normal chain, both the injected and normal chains are aborted, and both MCR[NSTART] and MCR[JSTART] are reset to 0.

60.3.8 Configuring ADC clock divider and sample time settings

You can scale the AD_clk frequency via MCR[ADCLKSEL]. ADCLKSEL can only be written in Power Down state (MCR[PWDN] = 1). Depending on the frequency of the module clock, there might be different settings necessary for functional conversion and for calibration. See the chip data sheet for ADC electrical characteristics.

Three conversion timing registers are used (CTR*n*) to support different sampling times for the different types of channels. An exception exists for the temperature sensor channel, which always uses the Conversion Timing For Standard Inputs (CTR1) value. See the register description for details.

60.3.9 Presampling

The presampling feature enables pre-charge or discharge of the ADC internal sample capacitor node to a defined level before sampling of the selected analog input channel starts. This is useful for resetting information (history effect/offset) from the most recent conversion. During presampling, ADC samples the internally generated voltage. During the sampling phase, ADC samples analog input coming from pads.

Enable presampling on a per-channel basis by setting the corresponding fields in the PSR*n* registers to one.

After enabling presampling for a channel, the normal sequence of operation for the channel is:

1. Presampling
2. Sampling
3. Evaluation

You can bypass sampling of all channels by writing 1 to PSCR[PRECONV]. When sampling of a channel is bypassed, the sampled and stored internal voltage applied during the presampling phase is converted (Figure 252). See Conversion time for the timing equation for conversion.

Presampling does not apply for self-test channels.

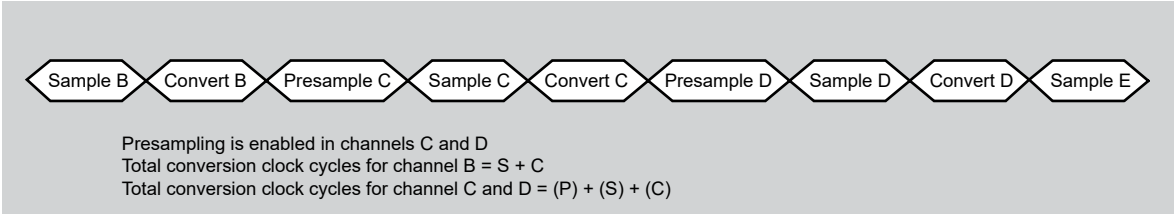

Figure 252. Presampling sequence

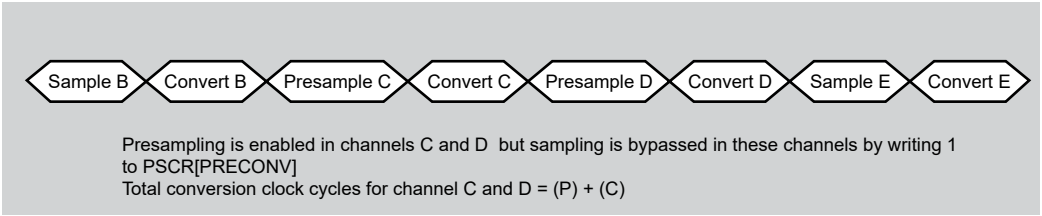

Figure 253. Presampling sequence with PRECONV=1

60.3.9.1 Enabling presampling per channel

Enable presampling for specific channels by programming Presampling Control (PSCR). You can select between two internally generated voltages by configuring the PREVAL*n* fields in Presampling Control (PSCR) to the appropriate values, as given in the following table.

Table 344. Presampling voltage selection via PREVAL*n*

PREVAL*n*	Presampling voltage
0	Presample voltage – 0: VREFL
1	Presample voltage – 1: VREFH

The presampling configuration field(s) (PSCR[PREVAL0], PSCR[PREVAL1], PSCR[PREVAL2]) are located in Presampling Control (PSCR). These fields enable selection of the presampling channel.

The temperature sensor channel has an exception. This channel is mapped with a fixed channel depending on device configuration, but it uses the presampling configuration defined for channel group 2. So, when the temperature sensor channel is selected, the presampling voltage defined by PSCR[PREVAL1] is selected. This voltage might be different from the one selected for channel group 1 via PSCR[PREVAL0].

60.3.10 Analog watchdog functions

When enabled, an analog watchdog monitors conversion results for an associated channel and reports an issue if it determines a result is outside customer-defined limits (as shown in Analog watchdog configuration (up to 16 watchdogs)). These limits are specified by an upper and a lower threshold value named THRH and THRL respectively.

After the conversion of the selected channel a comparison is performed between the converted value and the threshold values. If the converted value is outside that threshold value, then ADC generates a corresponding threshold violation interrupt.

The comparison result is stored as HAWIFx and LAWIFx fields in Analog Watchdog Threshold Interrupt Status (WTISR), as explained in the following table. Depending on the values of WTIMR[LAWIFENx] and WTIMR[HDWIFENx] mask fields, an interrupt is generated on a threshold violation.

Table 345. Values of HAWIFx and LAWIFx

HAWIFx	LAWIFx	Conversion result
1	0	Conversion result > THRH
0	1	Conversion result < THRL
0	0	THRH ≥ conversion result ≥ THRL

Depending on the chip's factory settings, up to 16 analog watchdogs are available. See the chip-specific configuration information for availability.

There are two types of mutually exclusive settings for analog watchdogs. Both types are described in the following sections. The availability depends on device configuration. See the chip-specific configuration information for availability.

Different capabilities are available with the two settings, as described below.

60.3.10.1 Channel analog watchdog select registers

ADC configuration includes selecting the analog watchdog threshold register (THRHLR*n*) that provides limits to monitor inputs of a given type. You select the THRHLR*n* using CWSELR*a*l*n* registers.

Table 346. CWSELR*a*l*n* register naming

Index	Description
a	ADC input type associated with a CWSELR*a*l*n* register. • P = Precision inputs • S = Standard inputs • E = External inputs
n	0-indexed register number.

60.3.10.2 Analog watchdog configuration (up to 16 watchdogs)

ADC can have up to 16 watchdogs in the factory configuration. (See the chip-specific configuration information for availability.) For each watchdog there is one threshold value register, THRHLR*n*, that contains the high and low thresholds.

You can independently enable the analog watchdog for each channel by programming the appropriate CWENR*n* register.

The threshold values for each channel can be selected independently from a maximum of 16 threshold registers (THRHLR*n*) using the corresponding WSEL_CH*n* field in the appropriate CWSELR*a*l*n*, where *a* indicates the input type:

- P = precision
- S = standard
- E = external

Each CWSELR*a*l*n* register is associated with 8 consecutive channels. CWSELR*a*l0 holds 8 WSEL_CH fields for channels 0 to 7. CWSELR*a*l1 is for channels 8 to 15 and so on. The availability of fields and registers depends on device configuration. See the chip-specific configuration information for availability.

If the conversion result of a selected channel is outside the range specified by threshold values, then the corresponding field in the Analog Watchdog Out of Range register (AWORR*n*) transitions to 1. For example, if channel 7 is to be monitored with the threshold values in THRHLR3, then CWSELR*a*l0[WSEL_CH7] must be programmed with 3. Enabling the watchdog is done by writing 1 to the corresponding field for channel 7 in CWENR0.

In this configuration, a set of threshold values (THRHLR*n*) can be linked to several ADC channels.

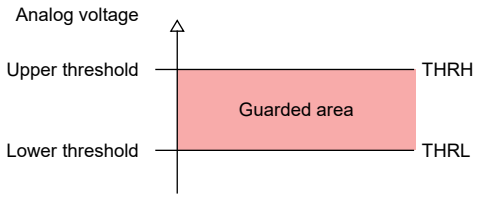

Figure 254. Guarded area

NOTE

If the higher threshold of the analog watchdog is programmed below the lower threshold and the conversion result is below the lower threshold, then the WDG*n*L interrupt for the low threshold violation transitions to 1. If the conversion result is greater than the lower threshold (and therefore also greater than the higher threshold), then the interrupt WDG*n*H for high threshold violation is generated. Thus you should take care to avoid that situation, as it could lead to misinterpretation of the watchdog interrupts.

60.3.11 DMA functionality

Conversion result data from any channel can be transferred from a register to system memory via Direct Memory Access (DMA). DMA transfers are enabled by writing 1 to DMAE[DMAEN]. After being enabled, the on-chip DMA controller can receive a DMA request after the conversion of each channel by writing 1 to the respective masking field in:

- DMA Request Enable For Precision Inputs (DMAR0)
- DMA Request Enable For Standard Inputs (DMAR1)
- DMA Request Enable For External Inputs (DMAR2)

DMA masking registers must be programmed before starting any conversion.

A DMA request to the DMA controller can be cleared at different times in two modes:

- Mode-1: Clearing of DMA request on acknowledgment from DMA controller (DMAE[DCLR] = 0)
- Mode-2: Clearing of DMA request on read to data registers (DMAE[DCLR] = 1)

The figures below show the operation of DMA in two modes (cycle counts are typical values).

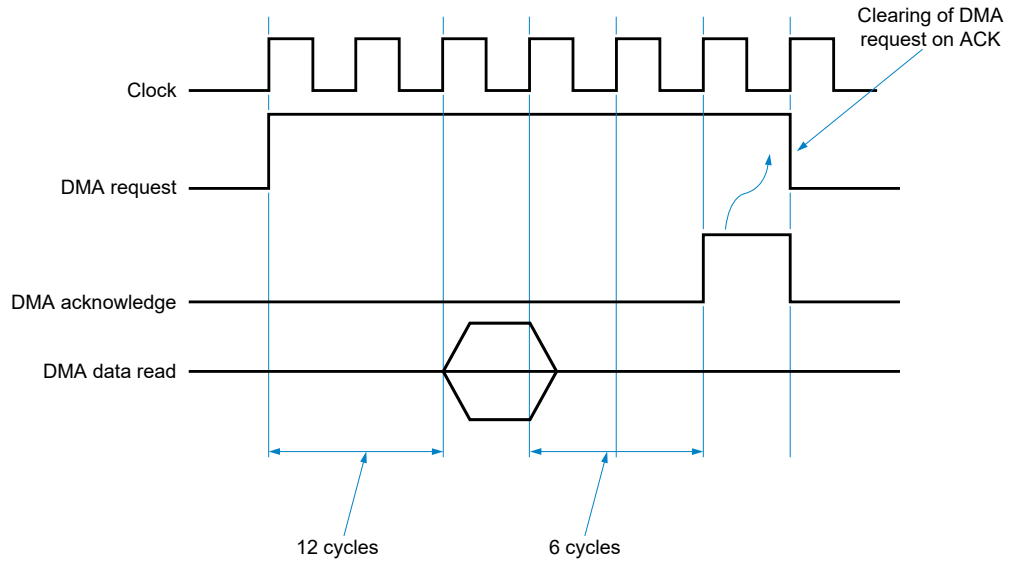

Figure 255. DMA operation Mode-1 (DMAE[DCLR] = 0)

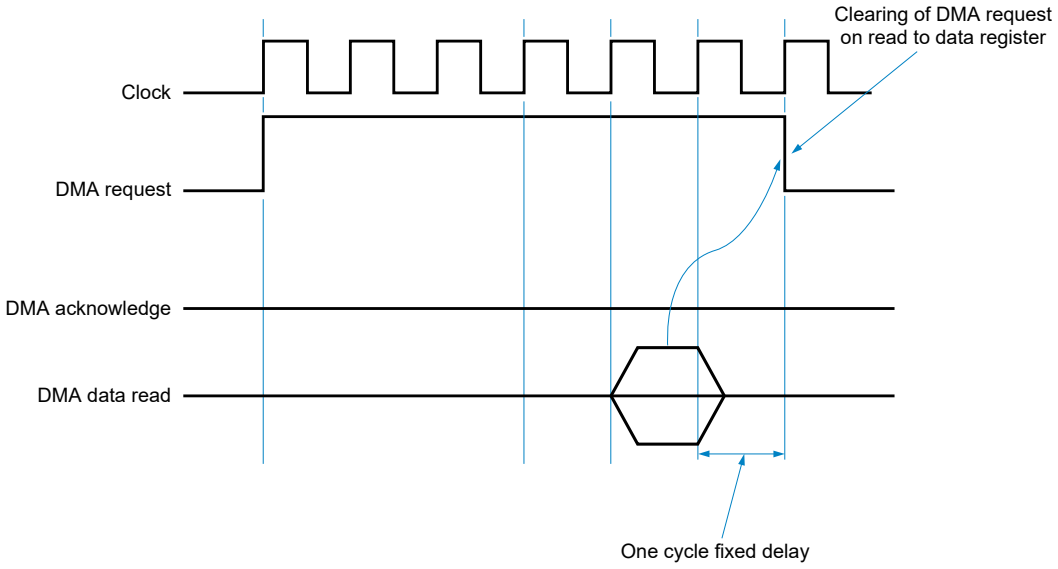

Figure 256. DMA operation Mode-2 (DMAE[DCLR] = 1)

60.3.12 Interrupts

ADC generates the following maskable interrupts:

- EOC (End of Conversion)
- ECH (End of Chain)
- JEOC (End of Injected Conversion)
- JECH (End of Injected Chain)
- EOBCTU (End of BCTU-triggered Conversion)
- LAWIFx and HDWIFx (Watchdog threshold)

- Self-testing interrupts

Interrupts are generated during the conversion process to signal events such as End Of Conversion (EOC), and so on, as described in Interrupt Status (ISR). ISR and another register, Interrupt Mask (IMR), are provided to check and enable the interrupt request to an external interrupt controller.

Interrupts can be individually enabled on a per-channel basis by programming EOC Interrupt Enable For Precision Inputs (CIMR0).

CEOCFR*n* are used for pending End of Conversion interrupts, with one field per channel to indicate completed conversions on a per-channel basis.

Interrupts generated due to the analog watchdogs are managed by two 32-bit registers, Analog Watchdog Threshold Interrupt Status (WTISR) and Analog Watchdog Threshold Interrupt Enable (WTIMR), to check and enable the interrupt request. A watchdog interrupt causes two corresponding fields to transition to 1 for each channel monitored. One field is in WTISR[WDG*n*H] and another in WTISR[WDG*n*L].

Generated events are logged into status registers and used to generate interrupts if enabled in corresponding Mask registers.

There are three different interrupt outputs. The interrupt structure is shown in Figure 257.

Each interrupt is generated by combining a group of events.

The following interrupts are combined (logic OR) into one interrupt output.

- EOC
- ECH
- EOBCTU
- JEOC
- JECH
- End of self-test algorithm (WDG_EOA_S and WDG_EOA_C)

Interrupts of all HDWIFx and LAWIFx are combined on the second interrupt output.

Interrupts of all self-test errors (watchdog threshold, sequence, and timer violations) in Self-Test Status 1 (STSR1) are combined on the third interrupt output. The errors are:

- WDSERR
- WDTERR
- ERR_S0
- ERR_S1
- ERR_S2
- ERR_C

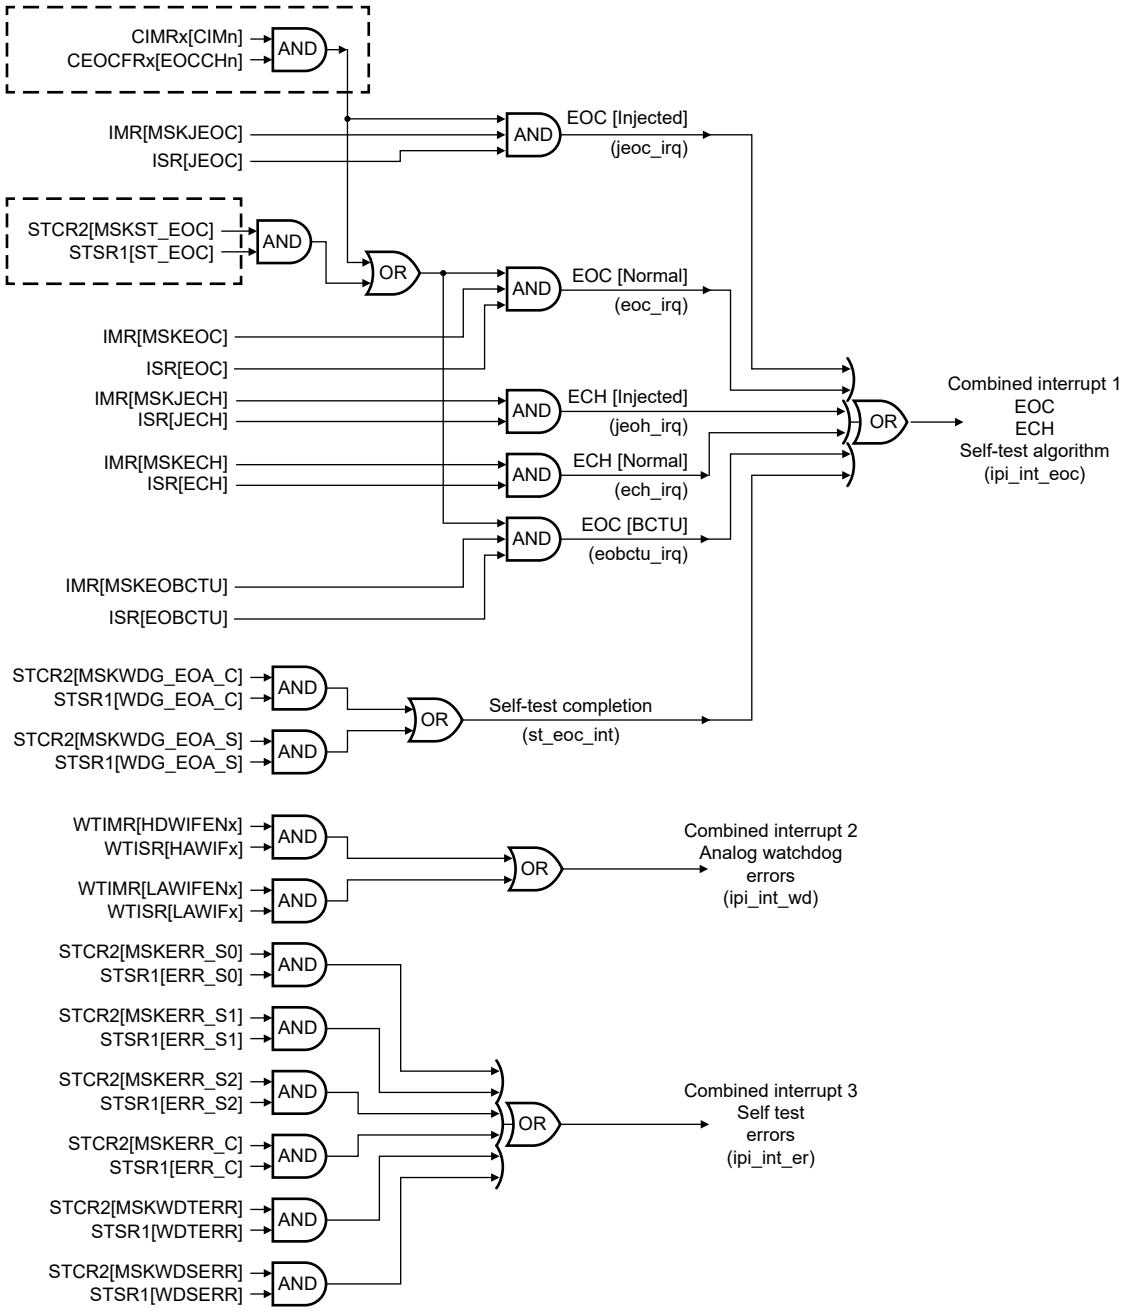

Figure 257. Interrupt structure of ADC

Interrupt Status (ISR) Indicates the interrupt pending request status. Write 1 to the corresponding status field to clear the pending interrupt flag (at this write operation all the other fields in Interrupt Status (ISR) must be maintained at 0).

ISR checks for three types of interrupts.

The first type, Interrupt 1, relates to the following:

- End of normal or injected conversion (EOC or JEOC)
- End of normal or injected conversion chain (ECH or JECH)
- End of algorithm C or algorithm S self-test (WD_EOA_C or WD_EOA_S)

Perform the following actions for this type of interrupt:

1. Read Interrupt Status (ISR) to determine whether the event is an EOC, JEOC, ECH, JECH, or EOBCTU event.
2. Read Self-Test Status 1 (STSR1) to identify the end of self-test algorithm events (WDG_EOA_S or WDG_EOA_C), if present.
3. If the interrupt is an EOC or JEOC event:
   - Clear the respective channel pending field in the appropriate CEOCFR*n* register for an EOC by writing a 1 to it.
   - Clear ISR[EOC] or ISRJEOC] by writing a 1 to it.
4. If the interrupt is an ECH or JECH, clear ISR[ECH] or ISR[JECH] by writing 1 to it.
5. If the interrupt is EOBCTU, clear ISR[EOBCTU] by writing 1 to it.
6. If the interrupt is for self-test end of algorithm, clear STSR1[WDG_EOA_S] or STSR1[WDG_EOA_C] by writing 1 to it.

The second type, Interrupt 2, relates to analog watchdog errors. Perform the following actions for this type of interrupt:

1. Read Analog Watchdog Threshold Interrupt Status (WTISR) to determine which watchdog triggered the interrupt.
2. Read the AWORRx register(s) to determine which channel's data caused the interrupt (if present).
3. Clear the respective field of the WTISR[WDG*n*H/WDG*n*L] register, where *n* = watchdog number, by writing 1 to it.
4. Clear the respective field of the AWORR*n*[AWOR_CH*n*] register, where x = register, n = channel, by writing 1 to it.

The third type, Interrupt 3, relates to self-test errors. Perform the following actions for this type of interrupt:

1. Read Self-Test Status 1 (STSR1) to determine the type of error encountered in self-test (WDSERR, WDTERR, ERR_S0, ERR_S1, ERR_S2, ERR_C, and so on) if present.
2. Clear the respective field in Self-Test Status 1 (STSR1) by writing 1 to it.

The connectivity of interrupt lines at the chip level (external to ADC) determines whether software must read all the registers for all three interrupts or any one or combination of any two.

60.3.13 External decode signals delay

The ADC provides three external decode signals which it uses to select one channel out of eight in the external analog multiplexers. There can be a maximum of four such multiplexers used to connect the 32 external channels. The ADC automatically sets the decode signals to control these external analog multiplexers, based on the current channel selected for conversion. Delay Start Of Data Conversion (DSDR) is provided to take the switching time of the external analog multiplexer into account. It enables you to program the delay between the decoding signal selection and the actual start of conversion.

If presampling is enabled, the DSD delay starts after the presample phase (presampling time is the same duration as sample time).

60.3.14 Power Down state

The analog part, along with the ADC controller, can be put in Power Down state by writing 1 to MCR[PWDN]. This shuts down ADC and stops the clock to the ADC controller. After release of reset, MCR[PWDN] remains 1, so the ADC analog module is kept in Power Down state by default. You must exit this state before starting any operation, by writing 0 to MCR[PWDN]. In Power Down state, no conversion can be started. If a BCTU trigger pulse is received during this state, it is discarded. You must ensure that a BCTU trigger is not initiated to ADC before writing 0 to MCR[PWDN], as it may cause the BCTU module to be stuck in a wait state.

You can set MCR[PWDN] by writing 1 to it at any time. If a conversion is ongoing, ADC does not move into Power Down state immediately. ADC enters Power Down state only after completion of the ongoing conversion. During scan operation, the ongoing operation should be aborted manually by writing 0 to MCR[NSTART] before or after writing 1 to MCR[PWDN].

ADC Power Down state status is indicated by MSR[ADCSTATUS] when ADC enters into Power Down state.

If the BCTU is enabled and MSR[BCTUSTART] = 1, then you cannot write 1 to PWDN. When BCTU Trigger mode is enabled, the application must wait for the end of conversion (MSR[BCTUSTART] is automatically reset to 0). When BCTU Control mode is enabled, before entering Power Down state the application must write 0 to BCTUEN also.

If Power Down state is entered by writing 1 to MCR[PWDN], the process running before entry into Power Down state must be restarted manually (by writing 1 to the appropriate START field in Main Configuration (MCR)) after exiting Power Down state.

NOTE

Writing 0 to MCR[PWDN] and writing 1 to MCR[NSTART] or MCR[JSTART] during the same cycle is not supported.

60.3.15 Low Power mode support

For low-power operation, ADC must be in Idle state and then put into Power Down state to ensure proper signal condition at the analog boundary.

From any of the states listed below, follow the sequence of steps shown to put ADC into Power Down state.

1. Idle condition
    a. Verify that ADC is in Idle state (MSR[ADCSTATUS] = 000b).
    b. Write 1 to MCR[PWDN], to shut off the clock to the hard macro with the proper state of signals required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).
2. During calibration

    NOTE

    Writing 1 to MCR[PWDN] during calibration is prohibited. After calibration is started it should be allowed to finish normally. Alternatively, it can be terminated by starting a normal conversion before writing 1 to MCR[PWDN].

    a. Check the current ADC state either via MSR[ADCSTATUS] (000b = Idle, 011b = Calibration), or via CALBISTREG[C_T_BUSY] (1 = calibration is in progress).
    b. When ADC is in Idle state, write 1 to MCR[PWDN] to shut off the clock to the hard macro with the proper state of signals required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).
3. During conversion (normal [one-shot]/Injected/BCTU):
    a. Write 1 to MCR[PWDN].
    b. ADC enters Power Down mode after completing the current conversion chain (for normal and injected conversions) or the conversion for conversion triggered by BCTU.
    c. Check the ADC state via MSR[ADCSTATUS] (000b = Idle state, 001b = Power Down state).
4. During Scan mode operation of normal conversion

    NOTE

    Writing 1 to MCR[PWDN] during scan mode operation has no effect other than to prevent software from starting a new normal or injected conversion. It does not stop a conversion in progress and cannot put ADC into Power Down state.

    a. Software must write 0 to MCR[NSTART] to stop the ongoing scan conversion before (or after) writing 1 to MCR[PWDN]. This stops conversion at the current chain boundary.
    b. ADC enters Power Down mode after coming to an Idle state after MCR[PWDN] is written with 1. This shuts the clock off to the hard macro and puts analog inputs in the proper state required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).

60.3.16 Auto Clock Off mode

To reduce power consumption during Idle state (without going into Power Down state), an auto-clock-off feature can be enabled by writing 1 to MCR[ACKO]. When enabled, the internal ADC operating clock (AD_Clk) is automatically switched off during an idle period (for example, no conversion is programmed).

60.3.17 Calibration and self-test

60.3.17.1 Calibration

ADC must be calibrated before it can do meaningful conversions. The application must prevent any start of conversion before the ongoing calibration has finished successfully. No conversion trigger may be received during calibration.

During calibration, a known reference voltage is sampled and converted under controlled conditions to determine the correction values (calibration values) for offset, gain, and capacitor mismatch.

These calibration values (except gain calibration) are used in a post-processing step after conversion, reducing or eliminating the various error contribution effects. The gain calibration is used during sample phase to define the additional charge to be loaded to compensate for gain failure.

You must run calibration after every power-up reset (check device-specific reset connectivity for appropriate reset applied). You must also run calibration if it is indicated by the self-test (see Self-test).

Configuration and start of calibration is done by programming the Control And Calibration Status (CALBISTREG). During calibration, internal hardware averaging function should be enabled. Maximum averaging is recommended, and 16 should be the minimum.

Calibration status is captured by a status flag (CALBISTREG[TEST_FAIL]) to indicate any fault detected during calibration execution or if calibration was prematurely aborted. Calibration is aborted if any normal conversion is initiated during the calibration execution, which is called premature termination. (Flag TEST_FAIL = 1 indicates a calibration fail, for example when a calibration value is out of internally defined limits.)

To execute the calibration algorithm, perform the following steps:

1. Select the conversion clock frequency to be within the allowed limits for the calibration.
2. Bring ADC from Power Down state to active conversion (program MCR[PWDN] = 0b).
3. Configure the Control And Calibration Status (CALBISTREG). The default values are set for maximum accuracy (recommended).
4. Disable the error correction for the smaller capacitances in the CDAC of the ADC (write 0h to CAL2[ENX]).
5. Start calibration (program CALBISTREG[TEST_EN] = 1b), and calibration starts immediately.
6. Poll the status of CALBISTREG[C_T_BUSY] for 0 (wait until it transitions to 0).
7. Check CALBISTREG[TEST_FAIL] to determine the final status. If 1, then calibration failed.
8. Check the status of MSR[CALIBRTD]. If calibration was successful this field is 1.

60.3.17.2 Self-test

For safety applications, it is important to verify correct operation at regular intervals. ADC has a self-test feature for this purpose. When self-test is enabled, ADC automatically checks its components and flags errors, if any are found.

Tests can be enabled to check the reference (VrefH) and calibrated values.

The following test algorithms have been implemented:

- Supply self-test (algorithm S): It includes the conversion of the band gap and VREF voltages. It includes a sequence of num_supply_steps test conversions (steps). The supply test conversions must be an atomic operation (that is, all supply algorithm conversions must be performed one after another with no functional conversions in between).

- Capacitive self-test (algorithm C): It includes a sequence of test steps per definition of algorithm C (see Table 347) which executes the capacitive matrix of the CDAC used for sampling and conversion.

Individual steps can take up to 1 µs at 80 MHz ADC clock frequency.

Table 347. Self-test steps

STCR3[ALG]	STCR3 [step](per algorithm definition)	Description	Outcome	Comment
00 (algorithm S)	0	Supply self-test (band gap voltage)	Measures the internal band gap voltage	
	1	Supply self-test (reference voltage high)	Measures ADC high reference voltage	
	2	Supply self-test (reference voltage high)	Measures ADC high reference voltage	
01 (Reserved)	Reserved			
10 (algorithm C)	0 – 11	Capacitive self-test. One of the calibration steps is being run.	The difference/error of the individual offset value from the previously calibrated value is being returned as an ADC result that is compared with the programmed value in the self-test analog watchdog register(s) to detect any fault.	The ideal result value is expected to be 0. If the returned value is higher, it indicates a runtime fault or accuracy shift. The error is indicated in the status register and can be used to generate an interrupt also. It that indicates ADC should be recalibrated to check whether the reported error can be managed by calibration or that permanent damage occurred to ADC.
11 (algorithm S + C)	0 – 2 (S), 0 – 11 (C)	Supply for One-Shot mode and (supply + capacitive) for Scan mode only.	Same as above.	

ADC:

- Schedules self-testing algorithms using configuration registers.
- Monitors the converted data using analog watchdog registers.
- Flags any errors to a fault control unit (FCCU), if one exists.

Self-test steps can be activated from software (CPU) or BCTU.

ADC mode	TEST algorithm (CPU)	TEST algorithm/step (BCTU)
CPU mode (MCR[BCTUEN] = 0)	Yes	No

Table continues on the next page...

Table continued from the previous page...

ADC mode	TEST algorithm (CPU)	TEST algorithm/step (BCTU)
	• One-Shot operation mode • Scan operation mode	
BCTU mode	No	Yes

60.3.17.2.1 CPU mode

In this mode, self-test conversion is similar to normal conversion. You enable self-test by writing 1 to STCR2[EN].

Self-test conversions execute along with the functional conversions. The sequencing of steps of the selected algorithm depends on the operating mode of normal conversions (selected by MCR[MODE]).

In One-Shot operation mode, if self-test is enabled, only one step of the selected self-testing algorithm is executed at the end of the chain. The step number and algorithm to be executed are programmed in Self-Test Status 3 (STSR3). In One-Shot operation mode the sequence is:

1. Program NCMR*n* to select channels to be converted for normal conversion.
2. Write 0 to MCR[MODE] to select one-shot operation.
3. Configure the self-test algorithm threshold values (see Table 348).
4. Program sampling duration values in STCR1[INPSAMP*m*] (*m* = S, C).
5. Select the self-testing algorithm (in STCR3[ALG]), and step (in STCR3[MSTEP]). The default is algorithm S, step 0.
6. Enable self-testing by writing 1 to STCR2[EN].
7. Start the normal conversion by writing 1 to MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of all normal conversions in the chain, the step number (programmed in STCR3[MSTEP]) of the self-testing algorithm (selected by STCR3[ALG]), is executed similar to a normal functional channel.
10. At the end of the conversion for the self-test channel:
    - The result is written to STDR1[TCDATA].
    - STDR1[VALID] transitions to 1.
    - ISR[EOC], ISR[ECH], and STSR1[ST_EOC] transition to 1.
11. ADC returns to Idle state.

For example: Channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in One-Shot operation mode. At the end of conversion for channels B→D→E, self-test conversion is performed and ISR[ECH] and ISR[EOC] transition to 1. The sequence is B→D→E→self-test step.

MSR[NSTART] transitions to 1 when the normal conversion starts and transitions to 0 at the end of conversion for the test channel.

In Scan operation mode, consecutive steps of the selected self-test algorithm are converted continuously at the end of each chain of normal conversions. The number of channels converted at the end of each chain is 1 (except for algorithm S, in which all the steps are performed sequentially without any functional conversion interleaved). So, in Scan operation mode the sequence is:

1. Program NCMR*n* to select the channels to be converted for normal conversion.
2. Write 1 to MCR[MODE] to select Scan operation mode.
3. Configure the self-test algorithm threshold values (see Table 348).
4. Program sampling duration values in STCR1[INPSAMP*m*] field (*m* = S, C).

5. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms (supply and capacitive) are selected, that is, all algorithms are executed step-by-step, one after the other.
6. Enable self-testing by writing 1 to STCR2[EN].
7. Start the normal conversion by writing 1 to MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of the chain of normal conversions (assuming the default value of STCR3[ALG]), all steps of algorithm S are performed (as algorithm S is always atomic). MSR[SELF_TEST_S] transitions to 1.
10. At the end of the conversion of the self-test channel for the last step of algorithm S, the result is written to STDR1[TCDATA] and STDR1[VALID] transitions to 1. At the same time, MSR[SELF_TEST_S] transitions to 0. The following registers also transition to 1:
    - ISR[EOC]
    - ISR[ECH]
    - STSR1[ST_EOC]
11. The next chain of normal conversions then starts.
12. At end of the chain of normal conversions, ADC executes step 0 of algorithm C.
13. At the end of the conversion of the test channel for step 0 of algorithm C, the result is stored in STDR1[TCDATA] and STDR1[VALID] transitions to 1 (if STSR1[OVERWR] is 1). Also, ISR[EOC] and ISR[ECH] transition to 1. STSR1[ST_EOC] also transitions to 1.
14. The next chain of normal conversion then starts.
15. At the end of the normal conversion chain, ADC executes step1 of algorithm C.

This process continues for all steps of all three algorithms. The state machine returns to Idle state when MCR[NSTART] transitions to 0.

For example: channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in Scan operation mode. At the end of every conversion chain for channels B→D→E, one step of the self-test conversion is performed and ISR[ECH] and ISR[EOC] transition to 1.

The sequence is:

B→D→E→ST-S0→ST-S1→ST-S2→B→D→E→ST-C0→B→D→E→ST-C1→B→D→E→ST-C2→ . . . B→D→E→ST-C11→B→D→E→ST-S0 . . .

ST-Sx - Self-test supply step x (x = 0, 1, 2)

ST-Cx - Self-test capacitive step x (x = 0 to 11)

MSR[NSTART] transitions to 1 when normal conversion starts.

NOTE

- If instead of starting normal conversion by software (by writing 1 to MCR[NSTART]), it is started by an external trigger, the self-test behavior remains the same.
- Self-test channel conversion is not performed for injected conversions. It is performed only during normal conversions.
- If, during a test channel conversion, an injected conversion arrives, the test conversion is aborted (just as a normal functional channel) and the injected conversion is performed. After the injected conversion is complete, the test conversion resumes from the step at which it was aborted. In this case, MSR[SELF_TEST_S] remains 1 during the injected conversion.
- For self-test, MCR[MODE] should be programmed (at least one cycle) before writing 1 MCR[NSTART] and should not be changed until the conversion is finished or terminated.

Table 348. Recommended self-test threshold values

Register field	Hex value	Decimal value	Comment
STAW0R[THRH]	3669h	13929	The threshold values depend on the stability of the supply and the reference voltage. When you see voltage variations, widen the limits.
STAW0R[THRL]	5 V reference: 1A7Fh 3 V reference: 2B27h	5 V reference: 6784 3 V reference: 11047	
STAW1R[THRL]	3FF9h	16377	
STAW2R[THRL]	3FF9h	16377	
STAW4R[THRH]	20h	32	
STAW4R[THRL]	7FE0h	–32	
STAW5R[THRH]	20h	32	
STAW5R[THRL]	7FE0h	–32	

60.3.17.2.2 BCTU mode

BCTU mode is enabled by writing 1 to MCR[BCTUEN].

Self-test conversion behaves in the same way for all BCTU operating modes (Trigger mode and Control mode). In both cases, if MCR[BCTUEN] = 1, the self-test conversion can be started only by BCTU—software cannot start it. MCR[BCTUEN] must not be changed during normal conversion. The interface between BCTU and ADC (for self-test) is shown in the following figure.

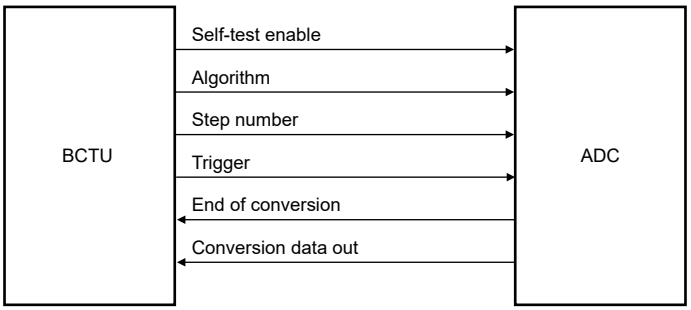

Figure 258. Self-test interface between ADC and BCTU

For self-test conversions in BCTU mode, BCTU asserts self-test enable along with the Trigger command. The algorithm and the step number to be executed is put on algorithm and step number, respectively. The other commands (Trigger, End Of Conversion, and Conversion Data Out) have the same meaning, like normal BCTU functional conversion.

As already mentioned for algorithm S, the three steps must be atomic. In BCTU mode, this is managed by BCTU, that is, BCTU sends three triggers (one for each step) asserting self-test enable and updating test_step for each step.

60.3.17.2.3 Abort and abort chain for self-testing channel

Writing 1 to MCR[ABORT] during self-test channel conversion has no effect.

In One-Shot operation mode, if you write 1 to MCR[ABORTCHAIN] during the self-test channel conversion, the self-test channel is aborted and ISR[ECH] transitions to 1. In this case, ISR[EOC] for the self-test channel is not generated.

In Scan operation mode, if MCR[ABORTCHAIN] = 1 when self-test channel step *n* is ongoing, self-test channel step *n* is aborted and the next chain conversion begins. At the end of the chain, the step *n* conversion is performed again. (For algorithm S, the full algorithm is executed again).

60.3.17.2.4 Self-test analog watchdog

ADC provides monitoring options for conversion data generated by self-test algorithms. Analog watchdogs determine whether the conversion results for self-test algorithms are in the range of a particular guard area. ADC provides separate self-test analog watchdog registers for each algorithm.

After the conversion of each step of a self-test algorithm, ADC compares the converted value and the threshold values if the analog watchdog feature has been enabled by writing 1 to STAW*n*R[AWDE] (for example, STAW0R[AWDE]). If the converted value is not between the upper and lower threshold values specified by the Self-Test Analog Watchdog Register for the particular algorithm, the corresponding error flag, STSR1[ERR_x], transitions to 1 and the step number in which error occurred is captured in STSR1[STEP_x] (for algorithm C). Erroneous data is written to STSR4[DATA*n*]. The STSR1[ERR_x] flags generate an interrupt if enabled by the corresponding mask bit in Self-Test Configuration 2 (STCR2). The fault indication is also forwarded to the fault control unit, if present, so that necessary action can be taken at the chip level. The fault type (critical or noncritical) is specified by the configuration in Self-Test Configuration 2 (STCR2).

The analog watchdog feature works differently for algorithm S. Algorithm S is always an atomic operation. Self-Test Status 1 (STSR1) has a separate error field for each step of algorithm S to avoid overwrite in case an error occurs in more than one step. Therefore, there are separate mask bits for each step in STCR1. For the same reason, the status registers (Self-Test Status 2 (STSR2) and Self-Test Status 3 (STSR3)) have separate fields for each step to store erroneous data.

In step 0 of the supply algorithm, ADC measures the band gap voltage (1.2 V), which is assumed to be stable. The conversion result of step 0 is compared against high (THRH) and low (THRL) thresholds as defined in Self-Test Analog Watchdog S0 (STAW0R), if enabled (STAW0R[AWDE] = 1). The STSR1[ERR_S0] flag transitions to 1 if any of the thresholds are violated. STSR1[ERR_S0] is cleared by writing 1 to it. The conversion result of ADC can be calculated with the following formula:

- ADC data (decimal) = (Vin × 2^{15} ÷ (Vrh - Vrl))

Where:

- Vin: input voltage (band gap voltage in this case)
- Vrh: ADC reference high voltage
- Vrl: ADC reference low voltage

The upper and lower threshold value can be calculated with the above formula using maximum and minimum values of Vin, Vrh, Vrl (Vin is the band gap supply voltage in this case):

- Upper threshold (THRH, decimal) = (Vin[max] × 2^{15}) ÷ (Vrh[min] - Vrl[max])
- Lower threshold (THRL, decimal) = (Vin[min] × 2^{15}) ÷ (Vrh[max] - Vrl[min])

The minimum and maximum voltages can be obtained from the chip data sheet. The band gap voltage tolerance, as well as the actual reference voltage used and its tolerances, must be considered when calculating high and low thresholds.

For algorithm S steps 1 and 2, (VREF/VREF) is measured in order to check the integrity of the sampling signal. For these particular conversions, no higher threshold value is required as the ideal value is FFFh. Only the lower threshold value is programmed in Self-Test Analog Watchdog S1 (STAW1R) and Self-Test Analog Watchdog S2 (STAW2R).

For algorithm C, a separate register is provided for step 0. In step 0 an offset for other steps is measured. The converted data is compared with the threshold values in Self-Test Analog Watchdog C (STAW5R) if STAW4R[AWDE] = 1. For other steps, this offset is subtracted from converted data before performing watchdog checks.

60.3.17.2.5 Watchdog timer

The watchdog timer is an additional check that monitors the sequence of the self-testing algorithm that has been implemented, and also checks whether the algorithm is completed within a safe time period. The watchdog timers are enabled for CPU as well as BCTU conversions. Each algorithm has an independent watchdog timer. The watchdog timer for a particular algorithm is enabled by writing 1 to STAWxR[WDTE]. The safe time value is programmed in STBRR[WDT] (the default value is 10 ms, assuming an 80 MHz clock).

The safe time is measured starting from step 0 of the algorithm (including all normal chain conversions in between) to the point where step 0 of the same algorithm starts again.

The programming sequence is:

1. Program NCMR*n* to select the channels for normal conversion in Scan operation mode (MCR[MODE] = 1).
2. Select the self-test algorithm in STCR3[ALG]. By default, all algorithms (supply and capacitive) are selected (all algorithms are executed step-by-step, one after the other).
3. Enable the self-test channel by writing 1 to STCR2[EN].
4. Program the safe period value in STBRR[WDT].
5. Enable the watchdog timer by writing 1 to STAWxR[WDTE]. Assume writing 1 to STAWxR[WDTE] occurs at time *t*0. It is important to do all configuration programming before writing 1 to STAWxR[WDTE], because the safe time check is also performed between writing 1 to STAWxR[WDTE] and the start of step 0. This is to verify that the algorithm has started within the safe time.
6. Start the normal conversion by writing 1 to MCR[NSTART].
7. At the end of the first conversion chain, three steps (steps 0, 1, and 2) of algorithm S are executed in sequence. Assume the start of Step 0 occurs at time *t*1.
8. After completion of algorithm S, ADC performs conversion of the next chain.
9. At the end of the conversion chain, the first step (step 0) of algorithm C is performed.
10. In this way, one step of algorithm C is performed after completion of one conversion chain until all steps are finished. Steps are executed in sequence (steps 0–11)
11. After the last step of algorithm C, another chain conversion is executed. At the end of this chain conversion, step 0 of algorithm S is started again, repeating the whole sequence. Assume this time (starting of step 0 of the supply algorithm) to be at time *t*2.
12. For algorithm S, if (*t*1 - *t*0) > safe period or (*t*2 - *t*1) > safe period, the watchdog timer flags an error and STSR1[WDTERR] transitions to 1. ADC asserts a fault signal per the criticality configuration (critical or noncritical) and an interrupt is generated, if enabled (STCR2[MSKWDTERR] = 1). Otherwise, the watchdog timer counter is reset and starts again to monitor the next sequence.
13. A similar sequence is followed for watchdog timers for algorithm C.

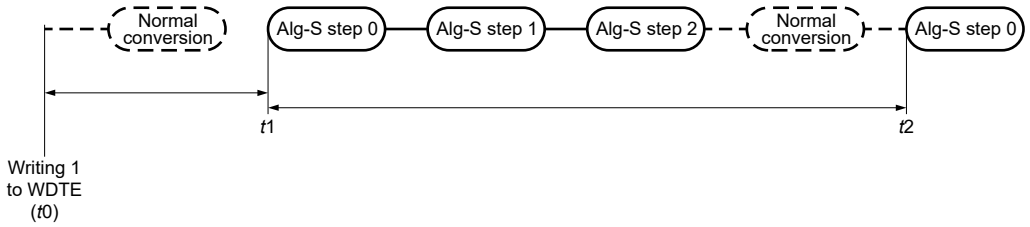

Figure 259. Watchdog timer monitor for algorithm S

NOTE

1. Because BCTU may not incorporate any safe period checking mechanism, the watchdog timers can also be enabled for BCTU conversions.
2. You must disable watchdog timers for self-test algorithms that are not executed.

60.3.17.2.5.1 Watchdog sequence checking

The self-test watchdog timer incorporates sequence checking features to verify that the steps of each algorithm are executed in the correct order. If the steps are not in the correct order, STSR1[WDSERR] transitions to 1 to indicate the error. A fault is indicated by an interrupt flag if STCR2[MSKWDSERR] = 1. A fault is also asserted as per criticality configuration (critical or noncritical) and an interrupt generated if STCR2[MSKWDSERR] = 1.

A watchdog sequence error is flagged in the following cases:

- The steps of any algorithm are not executed in proper order.
- The step numbers provided by BCTU for a BCTU conversion are not in order. Watchdog sequence checking is significant only for BCTU burst mode.
- When an abort chain occurs during a self-test channel conversion, that step must be repeated at the end of the next chain. This generates a sequence error as soon as the self-test channel conversion resumes. There is an exception, however. If an abort chain occurs during the last step of algorithm S, the sequence error is not flagged because the whole algorithm must be repeated.

If an injected conversion occurs during self-test channel conversion, a watchdog sequence error is not flagged, although the ongoing step number is aborted and is repeated.

NOTE

The watchdog timer feature is applicable for Scan operation mode but not for One-Shot operation mode.

60.3.17.2.6 Baud rate control for test channel

The baud rate control feature controls the scheduling of self-test channel conversions between normal conversion chains. The scheduling rate is specified by STBRR[BR].

By default, if the self-test channel is enabled, one step of the selected algorithm is executed after each normal conversion chain. The bandwidth consumed by the self-test channel depends on the number of channels in the normal chain. For example, if you have 50 normal conversions in a chain, then the self-test channel consumes only 2% of the total bandwidth, which is very small. If the number decreases to just 3 channels, the bandwidth consumed by the self-test channel is 25%, which is significant (and may not be desirable because it slows down the normal conversion rate).

STBRR[BR] provides flexibility by scheduling the self-test channel conversion to be performed not at the end of every chain, but at the end of BR + 1 chains. For example, if STBRR[BR] = 5, a single step of the selected algorithm for the test channel is performed after 6 chain conversions. The next step is performed at the end of the next six chain conversions, and so on. By default, STBRR[BR] = 0.

NOTE

This feature is applicable only for Scan operation mode and not for One-Shot operation mode. STBRR[BR] should be written with 0 for One-Shot operation mode.

To use the baud rate control feature in Scan operation mode, NCMR*n* should have a nonzero value.

60.3.17.2.6.1 Abort chain when baud rate is nonzero

As already described, for a nonzero value of STBRR[BR], the self-test channel conversion is performed at the end of BR + 1 chains. If an abort chain occurs during the chain in which a self-test channel conversion is scheduled to be performed, the self-test channel conversion is performed after the next BR + 1 chains.

For example, if STBRR[BR] = 2, the sequence is two normal chains (without any self-test channel conversion), followed by a chain with the self-test channel converted at the end. If an abort chain occurs during the first two chains, it is treated as a normal chain abort and the self-test channel is converted at the end of the third chain only (as in the case without any abort chain). However, if an abort chain occurs during the third chain in which the self-test channel is scheduled to be converted, the self-test channel is converted after the next three chains (for example, at the end of the sixth chain, counting from the beginning).

60.3.18 Conversion time

Total conversion time depends on the conversion clock frequency, which is configured by programming MCR[ADCLKSEL].

The components of conversion time and affecting configurations are:

- PST
- ST
- CT

- DP
- TPT

Presample phase time is equal to the sample time with a one AD_clk cycle delay for phase transition from presample phase to sample phase. CTR*n*[INPSAMP] controls sample time for different types of channels and is specified in terms of AD_clk cycles, so the presampling time is sample time plus one cycle of AD_clk. The minimum value of sample time is 8. If the value programmed is less than 8, it has no effect on sample time and the sample time is 8 AD_clk cycles.

Compare phase time is controlled by:

- The evaluation time of a single bit
- The number of bits converted

For *n*-bit conversions, the value of CT is *n* multiplied by the evaluation time of a single bit in terms of AD_clk cycles.

The evaluation time of a single bit is 4 AD_clk cycles if AMSIO[HSEN] = 0h and AMSIO[CMPCTRL0] = 0b. The evaluation time of a single bit is 6 AD_clk cycles if AMSIO[HSEN] = 1h and AMSIO[CMPCTRL0] = 1b.

The data processing time is 2 cycles of AD_clk. During these cycles raw converted data is corrected for offset, gain, capacitor mismatch, and so on.

Trigger processing time consists of:

- One module_clock cycle, which is required to prepare the channel and calculate the initial gain value used by ADC for the first conversion.
- BCTU triggering time:
  - Triggers from the synchronous BCTU interface require 1 cycle of the module clock for processing. One more cycle is required to register the BCTU trigger in synchronous mode.

The total conversion time, in terms of the module clock cycles, is calculated using the following equation for normal and injected conversions:

Total_conversion_time = ([(PST + ST + CT + DP) × chain_length] + TPT) × TAD_clk

Example:

The ADC controller clock is equal to the module clock (80 MHz, clock cycle = 12.5 ns)

- ADC resolution 12 bit + 1 bit for a special capacitor (CS)
- Three channels are programmed in NCMR*n*, so a chain of three is to be converted
- Default sample time (22 cycles) is specified
- No presampling
- Conversion time (4 cycles per bit)

The total time for the three conversions = [(0 + 22 + (4×13) + 2) × 3] + 1 = 229 cycles ~= 2.862 µs

Conversion timing in Calibration for full test:

- Single conversion time = [sample time (CALBISTREG[TSAMP]) + compare time (11 × 4) + data proc(2)]
- Inter-conversion gap = 1 cycle
- Total number of tests = 12
- Averaging = 32

One test duration = (single conversion time + inter-conversion gap) × averaging samples

Total test duration = ((one test duration) × total number of tests).

Example: sample time = 22

Total test time = ((((22 + (11×4) +2)+1) × 32) × 12) = 26496 cycles × 12.5 ns (80 MHz) = 331200 ns

Conversion time in self-test:

Self-test conversion time equals one test period multiplied by the number of consecutive (atomic) steps. For supply self-test, the atomic step is 3 and for other tests it is 1.

One test period for self-test is as below.

- For supply tests: ([sample_time + (13 × 4) + 2])
- For other algorithms: ([sample_time + (11 × 4) + 2])

NOTE

Algorithm S steps (conversions) always run in atomic operation, required for an algorithmic procedure. In Scan operation mode, when all algorithms are selected, three steps of algorithm S run together after the end of the conversion chain. algorithm C steps are not required to be run together, so after each conversion chain one step is executed serially. Conversion time with self-test must also be calculated accordingly.

Example.

- Channels in chain A→B→C.
- Scan operation mode.
- All self-test algorithms are selected.

So, the resulting conversion order is:

[A→B→C→AS_step0→AS_step1→AS_step2→A→B→C→AC_step0→A→B→C→AC_step1→A→B→C→AC_step2→.....→A→B→C→AC_step11]→[same sequence repeats]

NOTE

- AS = Algorithm S (supply self-test)
- AC = Algorithm C (capacitive self-test)

60.3.19 Conversion data processing

Raw converted data contains many types of errors, such as offset, gain, and so on. ADC processes raw conversion data before writing the result to a data register, to reduce or eliminate error contributions. The process of error correction happens in parallel with bit-by-bit evaluation, using the correction values generated during the offset determination and calibration process.

The error correction value is subtracted from the raw conversion result whenever the comparator output for one of the calibrated capacitors evaluates high during the conversion period.

To reduce data processing time, error correction is done in parallel during each bit evaluation of a conversion. Lower-weighted capacitors (smaller than C9) are not calibrated, so no error correction is performed for these capacitors. However, they are self-tested to guarantee that the error contribution is below specified accuracy limits.

The final result is checked for any overflow or underflow. When the processed data is above the maximum value that can be represented by ADC resolution, the output data is forced to all 1s (FFFh for 12-bit resolution). Similarly, if the processed data is negative then output data is forced to all 0s (000h for 12-bit resolution).

60.3.20 User-defined offset and gain values

In addition to the ADC-calculated offset value and gain value, ADC enables you to specify another set of offset and gain values in Offset And Gain User (OFSGNUSR). These values must be stored in two's complement format, where the leftmost bit (the most significant bit) is the sign bit.

ADC subtracts these values from the final processed conversion result. The values are used to removed fixed DC bias or any other known errors—for instance those caused by board design, sensors, and so on.

60.4 External signals

This module has no external signals.

60.5 Clock frequency

ADC's internal blocks are designed for an input clock frequency up to the Fin (Input Signal Bandwidth) maximum (see the ADC electrical specification section in the chip data sheet). The specified speed can be achieved with this clock frequency. If the input clock frequency exceeds the specified maximum frequency, ADC accuracy degrades and, in the worst case scenario, ADC malfunctions. ADC accuracy also degrades if the input clock frequency is below the specified minimum frequency. Sampling time has an absolute maximum value to guarantee the specified parameters and accuracy. For slower clocks, the sampling clock count must be programmed accordingly.

60.6 Memory map and register definition

ADC has a wide range of configurations to tailor its operation to application requirements. This comes with the drawback of possible corner cases. To avoid unintended behavior, configure ADC before starting a conversion and change any configuration only when ADC is idle, in other words when MSR[ADCSTATUS] = 0.

60.6.1 Transfer error description

The following register accesses cause a transfer error and do not change register content:

- Any access to an unused address.
- Any write access to a read-only register.

60.6.2.2 Main Configuration (MCR)

Offset

Register	Offset
MCR	0h

Function

Configures most ADC features. You must change field values only when ADC is in Idle state, except for the ABORTCHAIN and ABORT fields.

Diagram

Fields

Field	Function
31 OWREN	Overwrite Enable Specifies whether a conversion data register accepts new data before the current conversion data has been read. When enabled, the new conversion result overwrites the older data, regardless of the validity of the older conversion data. When PCDR*n*[VALID] = 1, the conversion data has not been read. 0b - Disable 1b - Enable
30 WLSIDE	Write Left-Aligned

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Specifies whether conversion data is right-aligned or left-aligned when written to one of the conversion data registers: • PCDR*n* • ICDR0*n* • ECDR*n* Right-aligned data occupies *CDR[14:0]. Left-aligned data occupies *CDR[15:1], 0b - Right aligned 1b - Left-aligned
29 MODE	Normal Conversion Mode Specifies whether the set of input channels selected for a normal conversion are converted only once per start event or continuously after a start event. If a conversion is done only once, ADC enters an idle state after conversion is complete. For continuous conversion, all input channels selected for the normal conversion are converted continuously in a loop. Stop the loop by writing 0 to NSTART. 0b - Single conversion 1b - Continuous conversion
28 —	Reserved
27 TRGEN	External Trigger Enable Specifies whether the normal trigger input starts a conversion. 0b - Normal trigger input does not start a conversion 1b - Normal trigger input starts a conversion
26 EDGE	External Trigger Edge Selection Selects which edge of the normal trigger input starts a conversion. 0b - Falling edge 1b - Rising edge
25 XSTRTEN	Auxiliary External Start Enable Enables the auxiliary normal trigger source to start a conversion. You can use this field to synchronize the start of a conversion of two ADC instances. 0b - Disable 1b - Enable
24 NSTART	Start Normal Conversion

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Starts a normal conversion. If the continuous mode is selected (MODE = 1), the value of this field remains 1. Write 0 to this field to stop the in-progress conversion loop after conversion of the last input channel of the selected set of input channels is complete. If continuous mode is not selected (MODE = 0), this field automatically resets to 0 after writing 1. 0b - No effect 1b - Starts conversion
23 —	Reserved
22 JTRGEN	Injection Trigger Enable Enables the injected trigger input as a source to start a conversion. 0b - Disable 1b - Enable
21 JEDGE	Injected Trigger Edge Selection Selects which edge of the injected trigger input starts an injected conversion. 0b - Falling edge 1b - Rising edge
20 JSTART	Injected Start Interrupts any ongoing normal conversion and starts an injected conversion. This field automatically resets to 0. If an injected conversion is already ongoing, the field value remains 1 until the next injected conversion starts. This field can only be written with 1. 0b - Injected conversion can be started 1b - Starts an injected conversion
19-18 —	Reserved
17 BCTUEN	Body Cross Trigger Unit Enable Enables BCTU as a trigger source. 0b - Disable 1b - Enable
16 BCTU_MODE	Body Cross Trigger Unit Mode Select Specifies whether sources other than BCTU can start a conversion when the BCTU is enabled as a trigger source (BCTUEN = 1). This field is writeable only when ADC is in Power Down state (PWDN = 1). 0b - Only BCTU can trigger conversion 1b - All trigger sources can trigger conversion

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 STCL	Self-Test Configuration Lock Protects the following registers from writing: • STCR1 • STCR2 • STCR3 • STBRR • STAW0R • STAW1R • STAW2R • STAW4R • STAW5R 0b - Registers are writeable 1b - Registers are read-only
14-12 —	Reserved
11 AVGEN	Averaging Enable Enables conversion averaging. 0b - Disable 1b - Enable
10-9 AVGS	Averaging Select Specifies the number of conversions ADC uses to calculate the conversion result. 00b - 4 conversions 01b - 8 conversions 10b - 16 conversions 11b - 32 conversions
8 —	Reserved
7 ABORTCHAIN	Abort Chain Aborts the conversion of the selected set of input channels (chain of input channels). The currently ongoing conversion completes. This field always reads 0. This field cannot be programmed during BCTU conversion.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Undefined When writing 0b - Conversion continues 1b - Conversion aborted
6 ABORT	Abort Conversion Aborts an ongoing conversion. This field always reads 0 and cannot be written during BCTU conversion. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Undefined When writing 0b - Conversion continues 1b - Conversion aborted
5 ACKO	Auto Clock Off Reduces power consumption by turning off the clock of the analog part of ADC when it is in Idle state. 0b - Clock always active 1b - Clock gated
4-3 —	Reserved
2-1 ADCLKSEL	Conversion Clock (AD_clk) Frequency Selection Selects the frequency for the clock signal of the conversion circuit (AD_clk = module clock ÷ ($2^{ADCLKSEL}$)). This field can be written only when ADC is in Power Down state (PWDN = 1). 00b - Module clock frequency 01b - Module clock frequency ÷ 2 10b - Module clock frequency ÷ 4 11b - Module clock frequency ÷ 8
0 PWDN	Power Down Reduces power consumption by turning off power to the analog portion of ADC.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - ADC enters a functional state 1b - ADC enters Power Down state

60.6.2.3 Main Status (MSR)

Offset

Register	Offset
MSR	4h

Function

Contains flags that indicate the current ADC state.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Function
31 CALIBRTD	Calibration Status Indicates ADC calibration status. 0b - Uncalibrated or calibration unsuccessful 1b - Calibrated
30-25 —	Reserved
24 NSTART	Normal Conversion Started Shows whether a normal conversion is in progress.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not in progress 1b - In progress
23 JABORT	Injected Conversion Aborted Indicates whether the conversion of a set of inputs selected for injected conversion has been aborted. This field resets to 0 when a new injected conversion is started. 0b - Not aborted 1b - Aborted
22-21 —	Reserved
20 JSTART	Injected Conversion Started Indicates whether an ongoing conversion was started by the injection trigger. 0b - Not an injected conversion 1b - Injected conversion
19 —	Reserved
18 SELF_TEST_S	Indicates whether an ongoing conversion is for self-test. 0b - Not self-test 1b - Self-test
17 —	Reserved
16 BCTUSTART	BCTU Conversion Started Indicates whether a BCTU conversion is ongoing. This field is 1 when a BCTU trigger event is received and the BCTU conversion starts. When the BCTU trigger mode is selected, this field is automatically reset to 0 when conversion is completed. Otherwise, if BCTU control mode is selected, this field resets to 0 when the BCTU is disabled (BCTUEN = 0). 0b - Conversion was not triggered by BCTU 1b - Ongoing conversion was triggered by BCTU
15-9 CHADDR	Input Under Measure Contains the number of the input that is currently converted. 000_0000b-011_1111b - Input number
8-6 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 ACKO	Auto Clock-Off On Indicates whether the auto clock-off feature is active, and the conversion circuit is not receiving a clock signal. When auto clock-off is inactive, the conversion circuit is clocked. 0b - Inactive 1b - Active
4-3 —	Reserved
2-0 ADCSTATUS	ADC State Indicates the current state of the ADC Finite State Machine (FSM). 000b - Idle 001b - Power Down 010b - Wait 011b - Calibrate 100b - Convert 110b - Done

60.6.2.4 Interrupt Status (ISR)

Offset

Register	Offset
ISR	10h

Function

Contains flags that indicate whether an interrupt has been generated.

60.6.2.12 Analog Watchdog Threshold Interrupt Status (WTISR)

Offset

Register	Offset
WTISR	30h

Function

Contains flags that indicate the result of a comparison between the conversion result and the threshold value defined in the analog watchdog.

60.6.2.23 Conversion Timing For Precision Inputs (CTR0)

Offset

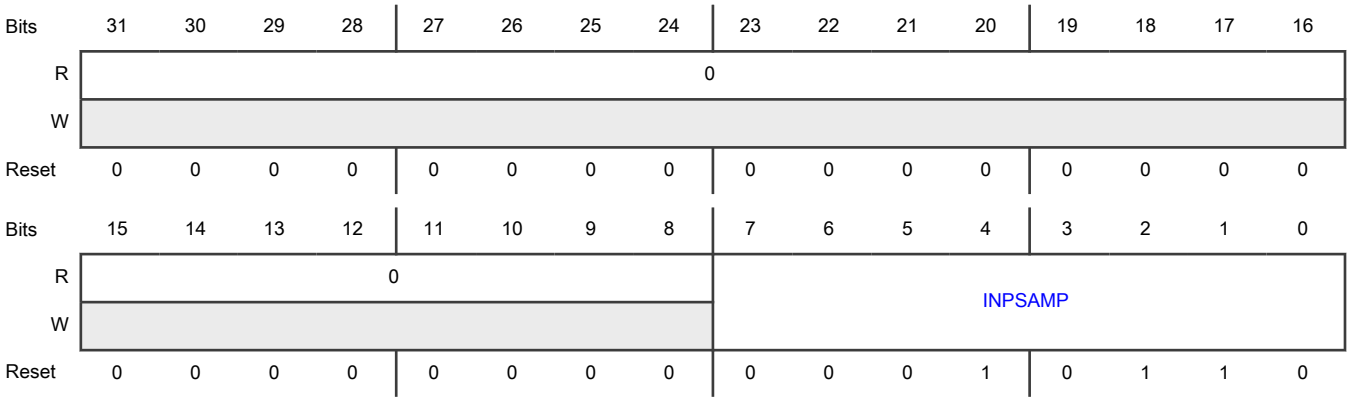
Register	Offset
CTR0	94h

Function

Specifies duration, in terms of the number of conversion clock cycles, of the sampling of precision inputs.

The conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 INPSAMP	Input Sample Cycles Specifies the sample duration in terms of conversion clock cycles. The minimum value is 8. Specifying a lower value automatically forces a value of 8.

60.6.2.24 Conversion Timing For Standard Inputs (CTR1)

Offset

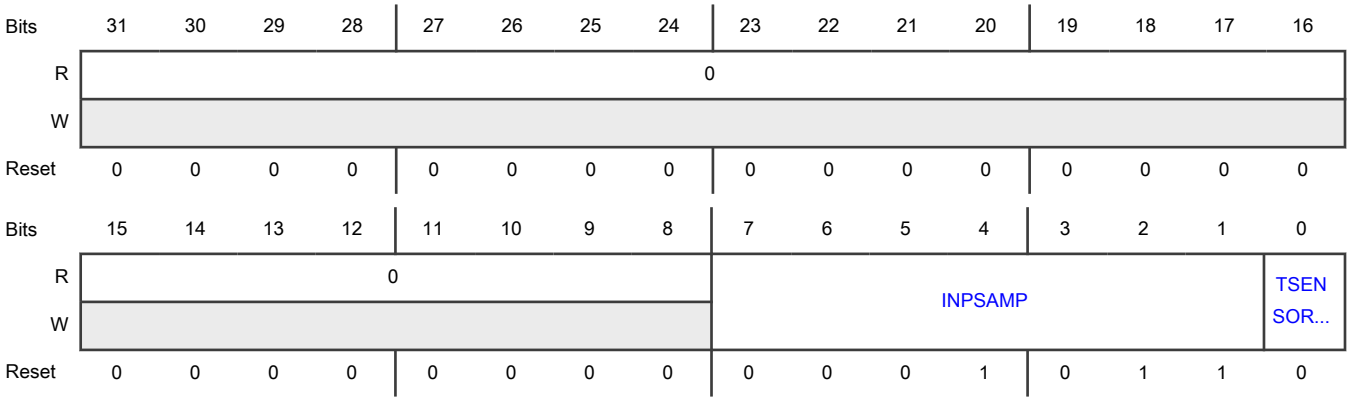
Register	Offset
CTR1	98h

Function

Specifies the duration, in terms of the number of conversion clock cycles, of the sampling of standard inputs or the temperature sensor.

The conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

Diagram



Fields

Field	Function
31-8 —	Reserved
7-1 INPSAMP	Specifies the sample duration in terms of conversion clock cycles. The minimum value is 8. Specifying a lower value automatically forces a value of 8. This field uses the TSENSOR_SEL bit as its low-order bit. In other words, INPSAMP is effectively an 8-bit field, but the low-order bit has a dual function.
0 TSENSOR_SEL	Temperature Sensor Voltage Select Selects the voltage for external temperature sensors (if available). If a temperature sensor is available, this field may be used as the selector for the mux between two temperature sensors. **NOTE** This field is applicable only when there is more than one temperature sensor. 0b - Selects temperature sensor source 0 1b - Selects temperature sensor source 1

60.6.2.25 Conversion Timing For External Inputs (CTR2)

Offset

Register	Offset
CTR2	9Ch

Function

Specifies the number of conversion clock cycles when the external inputs are sampled.

The conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

60.6.2.34 Precision Input n Conversion Data (PCDR0 - PCDR7)

Offset

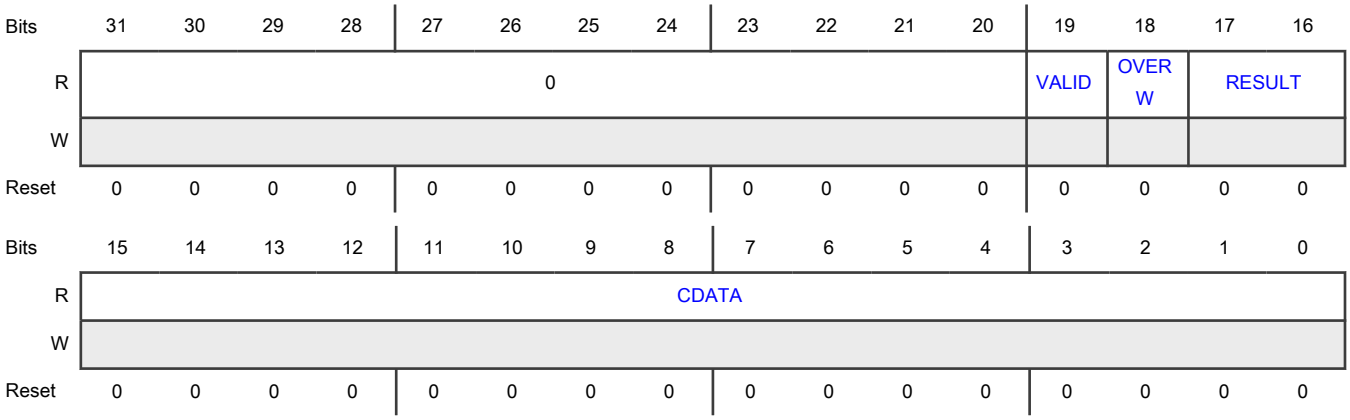
For n = 0 to 7:

Register	Offset
PCDRn	100h + (n × 4h)

Function

Contains conversion data from precision input *n*.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 VALID	Conversion Data Available Indicates whether new conversion data is available. This field is automatically reset to 0 when the data is read.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No unread conversion data 1b - Unread conversion data is available
18 OVERW	Overwrite Status Flag Indicates whether the previous conversion data was overwritten without having been read, in which case the overwritten data is lost. The ability to overwrite conversion data is controlled by MCR[OWREN]. 0b - No unread data is overwritten 1b - Unread data is overwritten
17-16 RESULT	Conversion Data Type Indicates the type of trigger that started the conversion for this conversion data. 00b - Normal trigger 01b - Injected trigger 10b - BCTU trigger
15-0 CDATA	Conversion Data Contains conversion data from precision input *n*, determined by the successive approximation algorithm. The conversion data is always 15 bits wide, regardless of the conversion resolution selected (CALBISTREG[RESN]). Depending on the value of MCR[WLSIDE], the conversion data can be in bits [14:0] (MCR[WLSIDE] = 0), or in bits [15:1] (MCR[WLSIDE] = 1).

60.6.2.35 Standard Input n Conversion Data (ICDR0 - ICDR23)

Offset

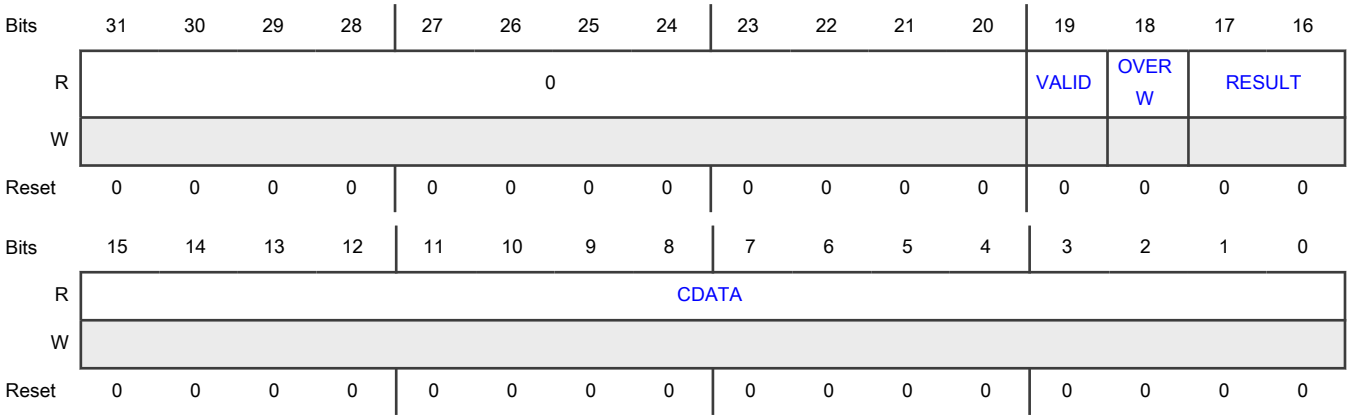
For a = 0 to 23:

Register	Offset
ICDRa	180h + (a × 4h)

Function

Contains conversion data from standard input *n*.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 VALID	Conversion Data Available Indicates whether new conversion data is available. This field is automatically reset to 0 when the data is read. 0b - No unread conversion data 1b - Unread conversion data is available
18 OVERW	Overwrite Status Flag Indicates whether the previous conversion data was overwritten without having been read, in which case the overwritten data is lost. The ability to overwrite conversion data is controlled by MCR[OWREN]. 0b - No unread data is overwritten 1b - Unread data is overwritten
17-16 RESULT	Conversion Data Type Indicates the type of trigger that started the conversion for this conversion data. 00b - Normal trigger 01b - Injected trigger 10b - BCTU trigger
15-0 CDATA	Conversion Data Contains conversion data from standard input *n*, determined by the SAR algorithm. The conversion data bit count is dependent on the conversion resolution selected (CALBISTREG[RESN]). Depending on the value of MCR[WLSIDE], the conversion data MSB bits start from 14 (MCR[WLSIDE] = 0), or 15 (MCR[WLSIDE] = 1).

60.6.2.36 External Input n Conversion Data (ECDR0 - ECDR31)

Offset

For a = 0 to 31:

Register	Offset
ECDRa	200h + (a × 4h)

Function

Contains conversion data from external input *n*.

NOTE

Each module instance supports a different number of registers.

CWSELRSI1	2C4h

Function

Selects the analog watchdog threshold register (THRHLR) that provides limits to monitor the standard inputs.

60.6.2.52 Self-Test Configuration 1 (STCR1)

Offset

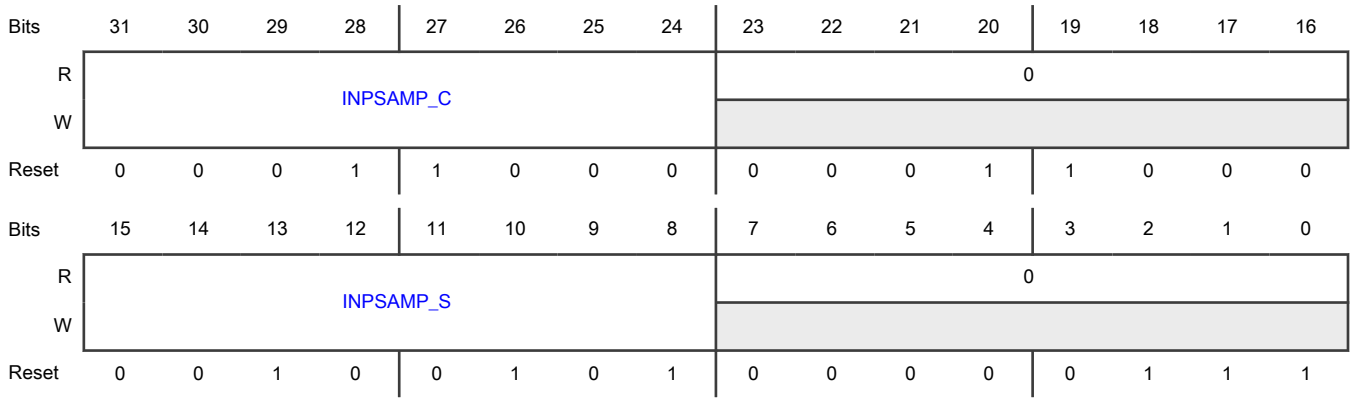
Register	Offset
STCR1	340h

Function

Specifies the input sampling duration in terms of conversion clock cycles.

Conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

Diagram



Fields

Field	Function
31-24 INPSAMP_C	Input Sampling Time Algorithm C Specifies the sample duration for test conversions related to algorithm C. The minimum acceptable value is 8. Specifying a lower value automatically forces a value of 8.
23-16 —	Reserved
15-8	Input Sampling Time Algorithm S

Table continues on the next page...

Table continued from the previous page...

Field	Function
INPSAMP_S	Specifies sample duration for test conversions related to algorithm S. The minimum value is 8. Specifying a lower value automatically forces a value of 8.
7-0 —	Reserved

60.6.2.53 Self-Test Configuration 2 (STCR2)

Offset

Register	Offset
STCR2	344h

Function

Configures ADC self-test functions.

Diagram

27 MSKWDSERR	Mask Interrupt Self-Test Watchdog Sequence Error Generates an interrupt when the WDSERR flag transitions to 1. 0b - No interrupt is generated 1b - Interrupt is generated

Table continues on the next page...

Table continued from the previous page...

Field	Function
26 SERR	Self-Test Error Injection Writes 1 to the STSR1[ERR_C], STSR1[ERR_S0], STSR1[ERR_S1], and STSR1[ERR_S2] status fields, causing an error. This field is reset to 0 immediately after writing. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Error can be injected 1b - Error is being injected When writing 0b - No effect 1b - Injects a self-test error
25 MSKWDTERR	Mask Interrupt Self-Test Watchdog Timer Error Generates an interrupt when the WDTERR flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
24 —	Reserved
23 MSKST_EOC	Mask Interrupt Self-Test End Of Conversion Generates an interrupt when the ST_EOC flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
22-19 —	Reserved
18 MSKWDG_EOA_C	Mask Error Interrupt End Of Algorithm C Generates an interrupt when the WDG_EOA_C flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
17 —	Reserved
16 MSKWDG_EOA_S	Mask Error Interrupt End Of Algorithm S Generates an interrupt when the WDG_EOA_S flag is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No interrupt is generated 1b - Interrupt is generated
15 MSKERR_C	Mask Error Interrupt Algorithm C Generates an interrupt when the ERR_C flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
14 —	Reserved
13 MSKERR_S2	Mask Error Interrupt Algorithm S2 Generates an interrupt when the ERR_S2 flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
12 MSKERR_S1	Mask Error Interrupt Algorithm S1 Generates an interrupt when the ERR_S1 flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
11 MSKERR_S0	Mask Error Interrupt Algorithm S0 Generates an interrupt when the ERR_S0 flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
10-8 —	Reserved
7 EN	Self-Test Enable Enables ADC structural self-test. When BCTU is enabled, this field has no effect. This field must be 1 before starting normal conversion and must not be changed during conversion. This field must be reset to 0 only after end of conversion for the last self-test channel has been received. 0b - Disable 1b - Enable
6-5 —	Reserved
4	Fault Mapping Self-Test Watchdog Sequence Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
FMA_WDSERR	Specifies whether a self-test watchdog sequence error sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line
3 FMA_WDTERR	Fault Mapping Self-Test Watchdog Timer Error Specifies whether a self-test watchdog timer error sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line
2 FMA_C	Fault Mapping Algorithm C Specifies whether a fault in algorithm C sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line
1 —	Reserved
0 FMA_S	Fault Mapping Algorithm S Specifies whether a fault in algorithm S sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line

60.6.2.54 Self-Test Configuration 3 (STCR3)

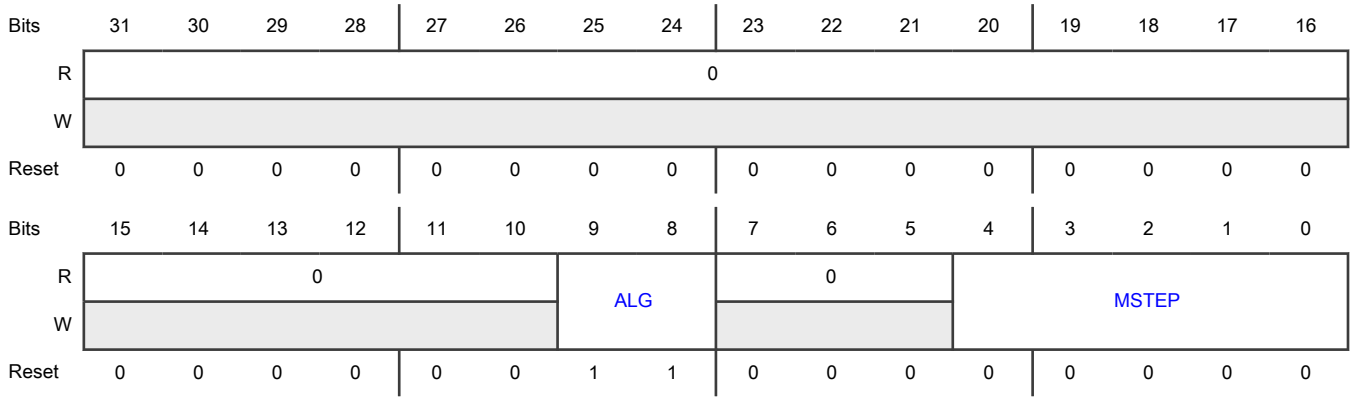
Offset

Register	Offset
STCR3	348h

Function

Configures ADC self-test functions. When BCTU is enabled, writes to the fields registers have no effect. This register must be programmed before starting a conversion and must not be changed when conversion is ongoing.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-8 ALG	Algorithm Selection One-Shot operation mode: • 00 Algorithm S (single step = MSTEP) • 01 Reserved • 10 Algorithm C (single step = MSTEP) • 11 Algorithm S (default) (use for test/debug purposes) Continuous conversion mode: • 00 Algorithm S • 01 Reserved • 10 Algorithm C • 11 Algorithm S + algorithm C (default)
7-5 —	Reserved
4-0 MSTEP	Algorithm Step For One-Shot operation mode: • MSTEP = 0 to 2 for algorithm S • MSTEP = 0 to 11 for algorithm C Unused codes are reserved and must not be used. For Scan operation mode:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is not used in Scan operation mode because single-step execution (interleaved mode) is always performed. This field must be programmed to zero in Scan operation mode.

60.6.2.55 Self-Test Baud Rate (STBRR)

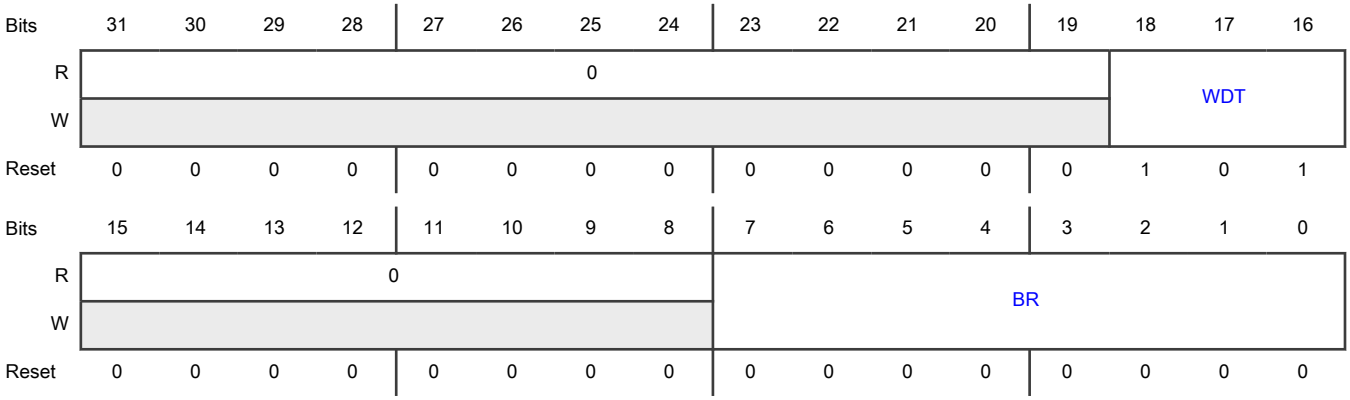
Offset

Register	Offset
STBRR	34Ch

Function

Specifies when the self-test algorithm steps are executed and the maximum time allowed for self-test to finish.

Diagram



Fields

Field	Function
31-19 —	Reserved
18-16 WDT	Self-Test Watchdog Timer Specifies the safe time period in terms of conversion clock cycles. The safe time period is the maximum duration until the running self-test is expected to finish. 000b - 8192 conversion clock cycles (~0.1 ms at 80 MHz) 001b - 39,936 conversion clock cycles (~0.5 ms at 80 MHz) 010b - 79,872 conversion clock cycles (~1 ms at 80 MHz)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	011b - 159,744 conversion clock cycles (~2 ms at 80 MHz) 100b - 400,384 conversion clock cycles (~5 ms at 80 MHz) 101b - 799,744 conversion clock cycles (~10 ms at 80 MHz) 110b - 1,599,488 conversion clock cycles (~20 ms at 80 MHz) 111b - 3,999,744 conversion clock cycles (~50 ms at 80 MHz)
15-8 —	Reserved
7-0 BR	Baud Rate Selects the number of conversions of the selected inputs, after which the next self-test algorithm step executes. This field must be programmed when STCR2[EN] is zero, that is, before enabling self-test. 0000_0000b - A step of the selected self-test algorithm is executed every time after the set of selected inputs has been converted. 1111_1111b - A step of the selected self-test algorithm is executed after the set of selected inputs has been converted 256 times.

60.6.2.56 Self-Test Status 1 (STSR1)

Offset

Register	Offset
STSR1	350h

Function
Indicates self-test status.

Diagram

Fields

Field	Function
31-28 —	Reserved
27 WDSERR	Self-Test Watchdog Sequence Error Indicates whether the selected self-test algorithm has executed in the correct sequence. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Algorithm executed in correct sequence 1b - Algorithm did not execute in correct sequence When writing 0b - No effect 1b - Clears flag
26 —	Reserved
25 WDTERR	Self-Test Watchdog Timer Error Indicates whether the self-test algorithm has finished within the defined safe time period. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Algorithm finished within the safe time period (or safe time period not yet elapsed). 1b - Algorithm did not finish within safe time period. When writing 0b - No effect 1b - Clears flag
24 OVERWR	Self-Test Error Status Overwrite Indicates whether an error occurred when the respective error status flag (ERR_S0, ERR_S1, ERR_S2, or ERR_C) was set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No self-test error status flag overwritten

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Self-test error status flag overwritten When writing 0b - No effect 1b - Clears flag
23 ST_EOC	Self-Test End Of Conversion Indicates whether a self-test conversion has completed. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clears flag
22-19 —	Reserved
18 WDG_EOA_C	Self-Test Watchdog End Of Algorithm C Indicates whether self-test algorithm C has completed. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clears flag
17 —	Reserved
16 WDG_EOA_S	Self-Test Watchdog End Of Algorithm S Indicates whether self-test algorithm S has completed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clears flag
15 ERR_C	Error Algorithm C Indicates whether an error occurred during execution of algorithm C. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clears flag
14 —	Reserved
13 ERR_S2	Error Algorithm S Step 2 Indicates whether an error occurred during execution of step 2 of algorithm S. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clears flag
12 ERR_S1	Error Algorithm S Step 1 Indicates whether an error occurred during execution of step 1 of algorithm S.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clears flag
11 ERR_S0	Error Algorithm S Step 0 Indicates whether an error occurred during execution of step 0 of algorithm S. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clears flag
10 —	Reserved
9-5 STEP_C	Step Of Algorithm C Indicates the step of self-test algorithm C in which an error occurred. Although this register field is read-only, no transfer error is generated when writing to it.
4-0 —	Reserved

60.6.2.57 Self-Test Status 2 (STSR2)

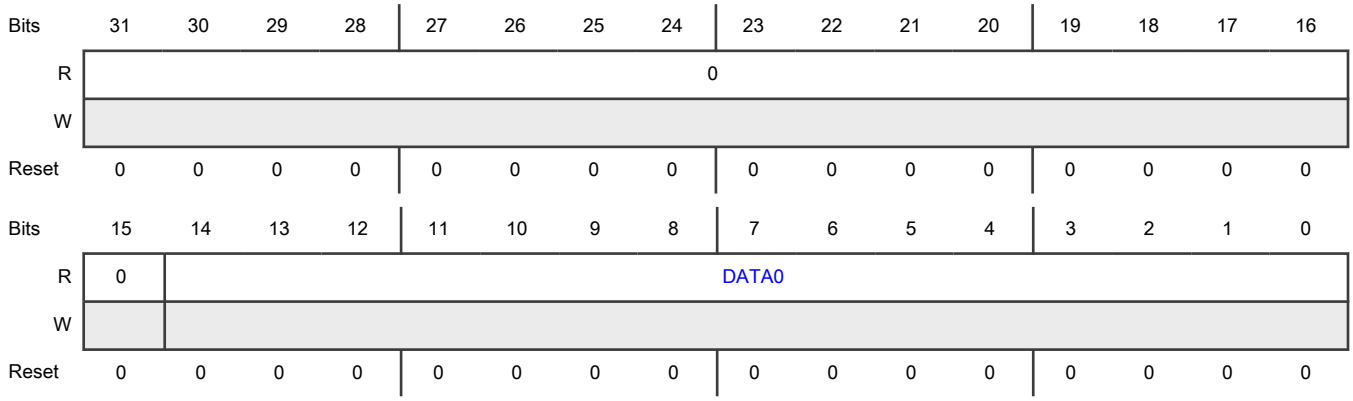
Offset

Register	Offset
STSR2	354h

Function

Contains the conversion result when an error in step 1 of algorithm S has occurred.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 —	Reserved
14-0 DATA0	Conversion Data ERR_S1 Contains conversion data from the moment when the error in step 1 of algorithm S has occurred.

60.6.2.58 Self-Test Status 3 (STSR3)

Offset

Register	Offset
STSR3	358h

Function

Contains the conversion result when an error has occurred in step 2 or step 0 of algorithm S.

Diagram

15 —	Reserved
14-0 DATA0	Conversion Data ERR_S0 Contains the conversion data from the moment when the error in step 0 of algorithm S has occurred.

60.6.2.59 Self-Test Status 4 (STSR4)

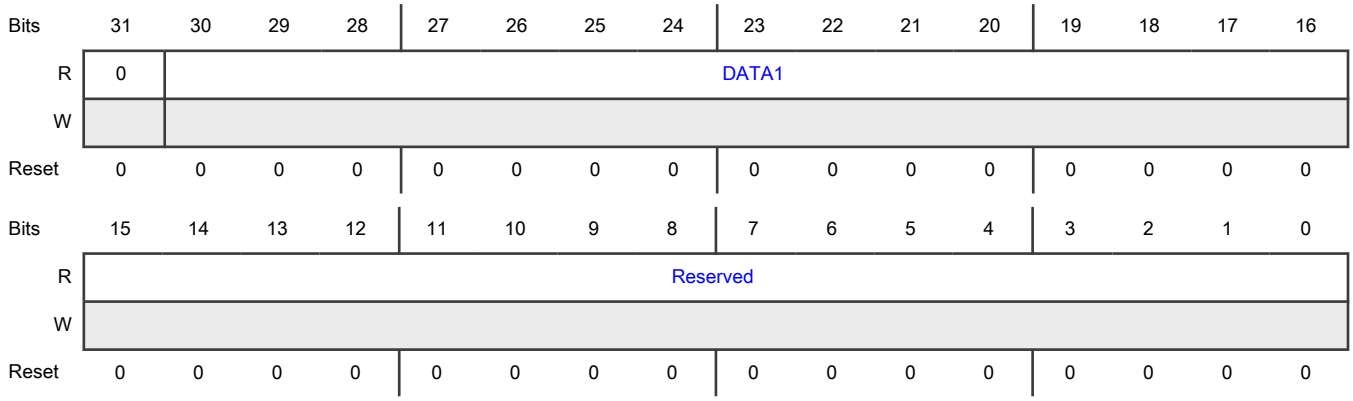
Offset

Register	Offset
STSR4	35Ch

Function

Contains the conversion result when an error has occurred in algorithm C.

Diagram



Fields

Field	Function
31 —	Reserved
30-16 DATA1	Conversion Data ERR_C Conversion data from the moment when the error in algorithm C has occurred.
15-0 —	Reserved

60.6.2.60 Self-Test Conversion Data 1 (STDR1)

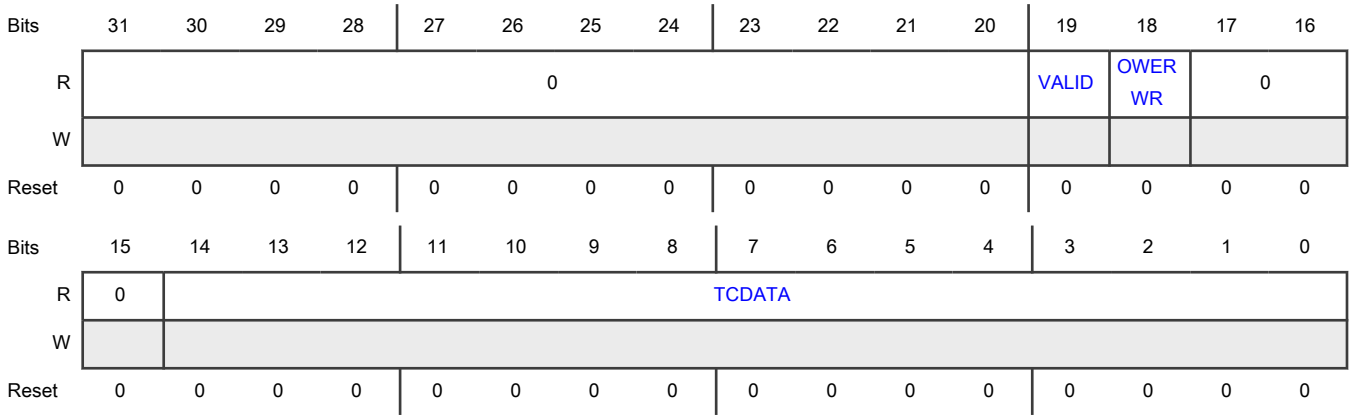
Offset

Register	Offset
STDR1	370h

Function

Contains the result of the self-test conversion.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 VALID	Valid Conversion Data Indicates that conversion data is available in TCDATA. This field is automatically reset to 0 when the conversion data is read. 0b - No unread conversion data 1b - Unread conversion data is available
18 OWERWR	Conversion Data Overwrite Status Indicates whether the conversion data in TCDATA has been overwritten over previous data that had not been read. 0b - Current conversion data not overwritten 1b - Current conversion data was overwritten
17-16 —	Reserved
15 —	Reserved
14-0 TCDATA	Test Channel Conversion Data Contains the conversion data from self-test. If overwrite is enabled (MCR[OWREN]=1), the conversion data is from the last-executed self-test conversion. When overwrite is not enabled, conversion data is available (not overwritten) until it is read by software. The conversion data in this register is in two's complement format.

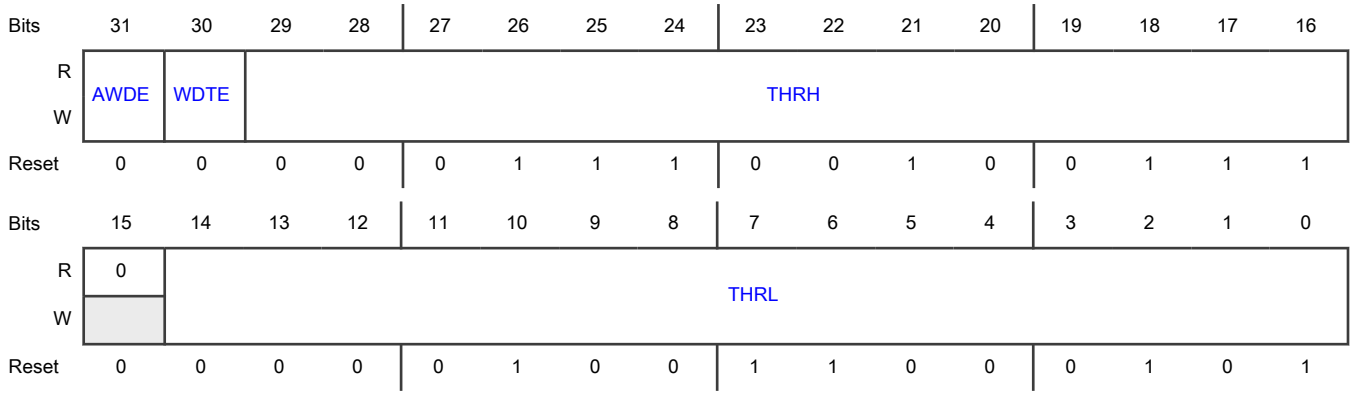
60.6.2.61 Self-Test Analog Watchdog S0 (STAW0R)

Offset

Register	Offset
STAW0R	380h

Function
Configures self-test for step 0 of algorithm S.

Diagram



Fields

Field	Function
31 AWDE	Self-Test Watchdog Enable Enables the self-test watchdog for step 0 of algorithm S. 0b - Disable 1b - Enable
30 WDTE	Self-Test Watchdog Timer Enable Enables the self-test watchdog timer for algorithm S. The self-test watchdog timer verifies: • Correct sequence of execution of the steps of the algorithm • Execution of the algorithm within the safe time period as defined by STBRR[WDT] This field must be 1 only in continuous conversion mode (MCR[MODE]=1). The safe time period starts when this field is written with 1. If the safe time period has elapsed before algorithm S starts, the WDTERR flag is set. The safe time period is restarted each time algorithm S starts. 0b - Disable 1b - Enable
29-16	Higher Threshold Value

Table continues on the next page...

Table continued from the previous page...

Field	Function
THRH	Sets the ERR_S0 flag when a self-test conversion value is greater than this value.
15 —	Reserved
14-0 THRL	Lower Threshold Value Sets the ERR_S0 flag when a self-test conversion value is less than this value.

60.6.2.62 Self-Test Analog Watchdog S1 (STAW1R)

Offset

Register	Offset
STAW1R	388h

Function
Configures self-test for step 1 of algorithm S.

30	Self-Test Watchdog Timer Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
WDTE	Enables the self-test watchdog timer for algorithm C. The self-test watchdog timer verifies: • Correct sequence of execution of algorithm steps • Execution of the algorithm within the safe time period as defined by STBRR[WDT] This field must be 1 only in continuous conversion mode (MODE 1). The safe time period starts when this field is written with 1. If the safe time period elapses before algorithm C starts, the WDTERR flag is set. The safe time period is restarted each time algorithm C starts. 0b - Disable 1b - Enable
29-16 THRH	Higher Threshold Value Sets the ERR_C flag when a self-test conversion value is greater than this value. This value must be in two's complement format and must be positive. This value is valid only for step 0 of algorithm C (see STAW5R for the values used for the other steps of algorithm C).
15 —	Reserved
14-0 THRL	Lower Threshold Value Sets the ERR_C flag when a self-test conversion value is less than this value. This value must be in two's complement format and must be negative. (With the reset value of this bit field, the test always fails. You must set at least STAW4R[14]=1, in order to have a negative value in this bit field.) This value is used only for step 0 of algorithm C (see STAW5R for the values used for the other steps of algorithm C).

60.6.2.67 Control And Calibration Status (CALBISTREG)

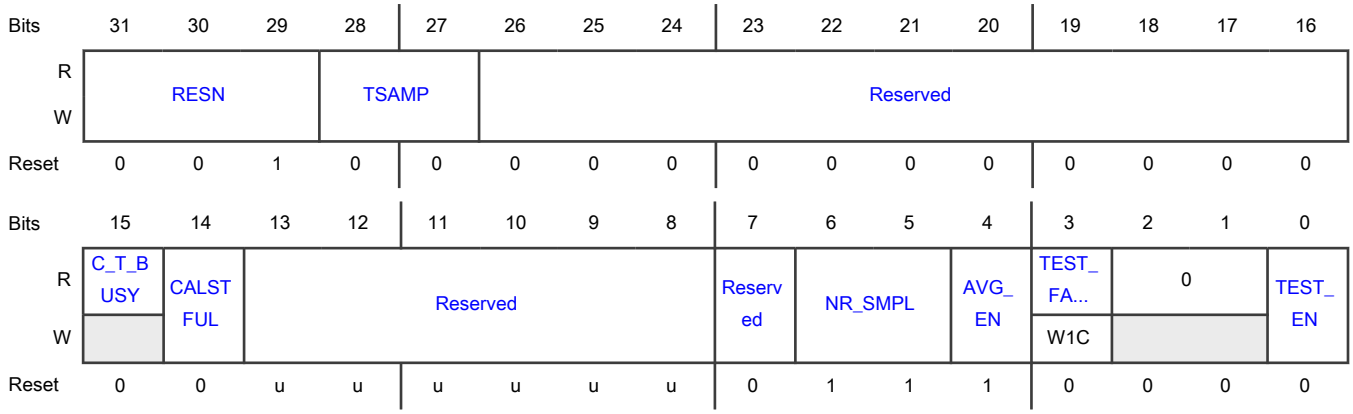
Offset

Register	Offset
CALBISTREG	3A0h

Function

Controls several ADC functions for data conversion, calibration, and calibration status.

Diagram



Fields

Field	Function
31-29 RESN	Conversion Resolution Specifies the number of significant bits per conversion data (functional conversion only, not for calibration or self-test). Reducing this number speeds up the conversion because the SAR algorithm executes fewer steps. This field must be modified only when ADC is idle. 000b - 14-bit resolution 001b - 12-bit resolution 010b - 10-bit resolution 011b - 8-bit resolution
28-27 TSAMP	Sample Period In Calibration Specifies the number of conversion clock cycles during which the reference voltage is sampled. 00b - 22 conversion clock cycles 01b - 8 conversion clock cycles 10b - 16 conversion clock cycles 11b - 32 conversion clock cycles

Table continues on the next page...

Table continued from the previous page...

Field	Function
26-16 —	Reserved The value of this field must not be modified.
15 C_T_BUSY	Calibration Busy Indicates whether calibration is running. 0b - Calibration can be started 1b - Calibration is in progress
14 CALSTFUL	Calibration And Self-Test Full Range Comparison Specifies the range of conversion data bits compared when ADC is calibrated or running self-test. Because the results from calibration and self-test are so low that the significant bits are in the lower 11 bits only, the comparison cycles for the upper 4 bits can be skipped to reduce the execution duration of the calibration and of the self-test. 0b - Lowest 11 bits are compared. 1b - All 15 bits are compared.
13-8 —	Reserved **CAUTION** This field contains a value that ADC uses internally. Writing to this field can cause ADC to operate unreliably.
7 —	Reserved This field is reserved and always has the value 0. Only the reset value can be written to this field.
6-5 NR_SMPL	Calibration Averaging Number Specifies the number of data conversions per result (averaging) during calibration. 00b - 4 samples 01b - 8 samples 10b - 16 samples 11b - 32 samples
4 AVG_EN	Calibration Averaging Enable Enables averaging of the calibration results over several conversion iterations to improve accuracy. This field only affects the calibration process. 0b - Disable 1b - Enable
3 TEST_FAIL	Calibration Status Indicates calibration status. This field reads 0 when calibration is in progress. This field is reset to 0 when calibration starts.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Calibration finished successfully or has not been run since the last reset 1b - Calibration did not finish successfully When writing 0b - No effect 1b - Clears flag
2-1 —	Reserved
0 TEST_EN	Calibration Enable Calibrates ADC. This field automatically resets to 0 after the calibration is complete or is interrupted. 0b - Wait to start a calibration 1b - Start calibration

60.6.2.68 Offset And Gain User (OFSGNUSR)

Offset

Register	Offset
OFSGNUSR	3A8h

Function

Specifies the user-configured offset and gain values used by the SAR algorithm. The values must be written in two's complement format and can be either positive or negative.

Chapter 61
Low Power Comparator (LPCMP)

61.1 Chip-specific LPCMP information

61.1.1 Instantiation information

Table 349. LPCMP instances

Chip	Instance	No. of external inputs
S32K388/S32K389/S32K358/S32K348/ S32K338/S32K328/S32K344/S32K324/ S32K314	LPCMP_0	8
	LPCMP_1	4
	LPCMP_2	4
S32K312/S32K342/S32K322/S32K341	LPCMP_0	8
	LPCMP_1	4
S32K311/S32K310	LPCMP_0	8

61.1.2 LPCMP input output connections

See the IOMUX file attached to this document for pin/pad assignments corresponding to CMP pins.

The LPCMP channels can be used as a wakeup source in trigger mode to wakeup the device from standby mode.

61.1.3 LPCMP-DAC "vrefh0" and "vrefh1" references

The 8-bit DAC sub-block supports selection of "vrefh0" and "vrefh1" by CMPx_DCR[VRSEL]. For this device, the references are connected as follows:

- vrefh0 (External Reference): VDD_HV_A
- vrefh1 (Internal Reference): 1.2 V PMC bandgap reference

NOTE

1.2 V internal reference voltage is not available in Standby mode.

61.1.4 LPCMP window control

The window mode operation of all the comparator instances in the chip can be enabled/disabled by the TRGMUX. See the TRGMUX connectivity file attached to this document for details.

NOTE

Window signal must be of minimum 4 cycle pulse for window mode to function.

61.1.5 Comparator Trigger Mode

The comparator modules in the device support trigger mode operation as described in 'Trigger Mode' section. Device can operate in trigger mode in both standby and run mode to continuously scan the input channels. The main features of the device trigger mode operation are:

- Round robin clock: RTC_CLK
- Round robin trigger source: RTC_API

NOTE

- It must be ensured that the RTC_CLK period is greater than the comparison time corresponding to the value of C0[PMODE]. It is also required to **not** select the internal reserved channels, if available on the package, for trigger mode operation by INPSEL and INNSEL. See the IOMUX file attached to this document for the pins available in various packages supported for the device.
- Only SIRC and SXOSC are supported as RTC_CLK for trigger mode operation. The LPCMP initialization delay is not supported by RRCR0[RR_INITMOD] with FXOSC or FIRC as RTC_CLK.
- In run mode, the generated trigger is delayed by 3 RTC_CLK cycles before being given to comparator trigger input.
- When used in Round Robin mode, the LPCMP outputs the enable signal of the comparator on CMPx_RRT pin, on each cycle of comparator circuit. See the IOMUX file attached to this document for the pins on which CMPx_RRT functions are available.

61.1.6 Interaction with RTC API to cause wakeup

LPCMP can be used for waking up the chip from standby. For this, RTC-API and LPCMP must be configured before entering into standby mode as per below shown figure.

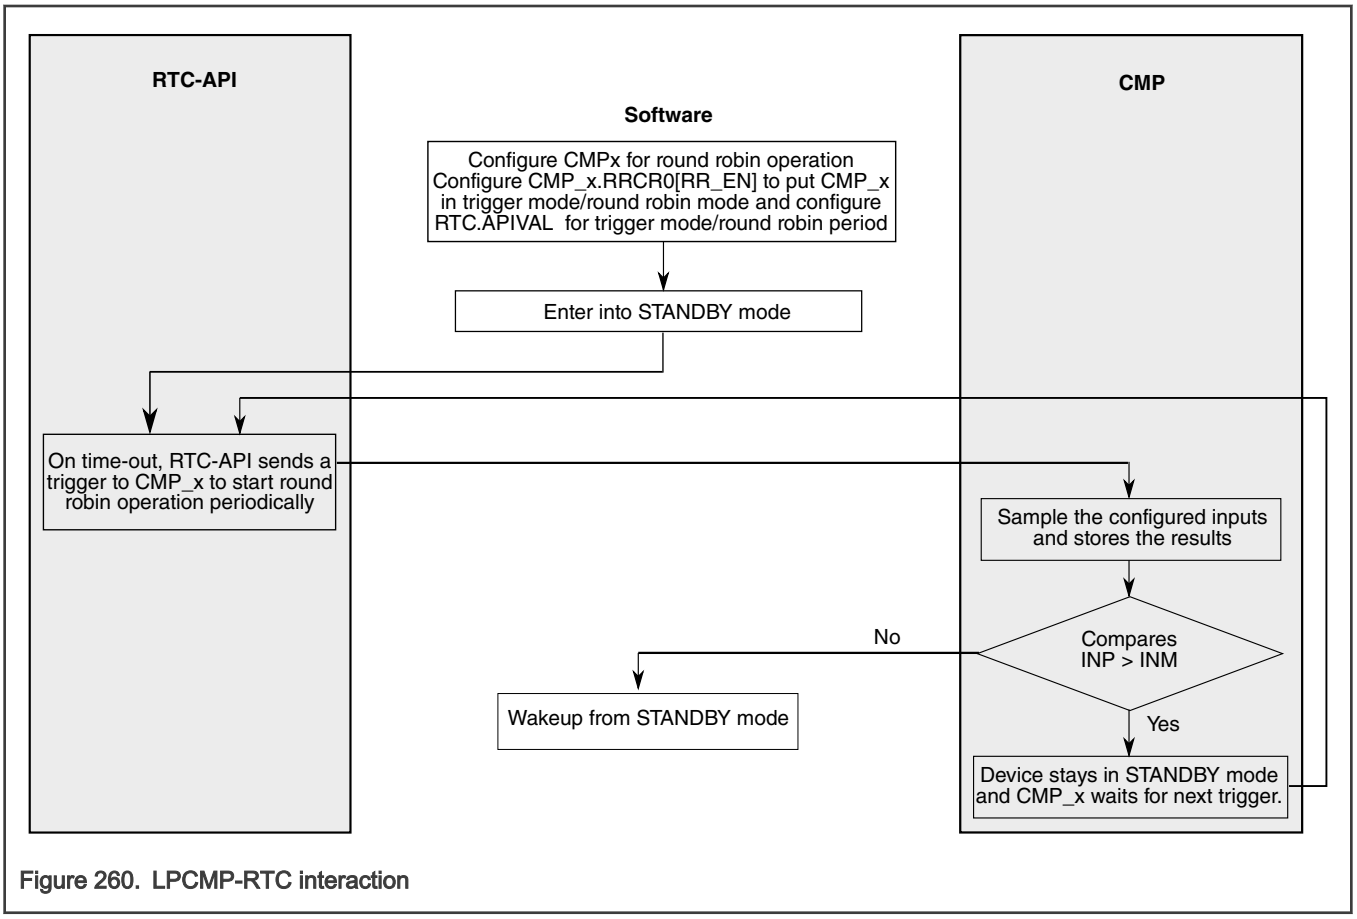

Figure 260. LPCMP-RTC interaction

In the trigger mode operation, only the continuous mode is supported. None of the window/filter/sample functions should be used. Refer to the "Functional Modes" section for details on comparator modes of operation.

Register configurations before entering Standby mode for LPCMP trigger mode operation:

1. Configure RTC.APIVAL to set the period of the round robin operation.
2. Execute standby mode entry.

61.2 Overview

The LPCMP module provides a circuit to compare two analog input voltages. It includes the following:

- A low power comparator (CMP)
- A DAC
- An analog mux (ANMUX)

See Block diagram for more information.

LPCMP can operate across the full range of the supply voltage, known as rail-to-rail operation.

DAC is a 256-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. DAC divides the supply reference V_{in} into 256 voltage levels. An 8-bit digital signal input selects the output voltage level, which varies from V_{in} to $V_{in}/256$.

You can select V_{in} from the following voltage sources:

- VREFH0
- VREFH1

See the Chip-specific LPCMP information for more information on source of VREFH0 and VREFH1.

NOTE

The LPCMP's internal DAC output is available as an on-chip internal signal only and is not available for an external chip pin.

ANMUX allows you to select an analog input signal from among eight channel options. One channel option is the DAC output. Other chip resources are connected to the other channels. See the Chip-specific LPCMP information section for more information. ANMUX can operate across the full range of the supply voltage.

61.2.1 Block diagram

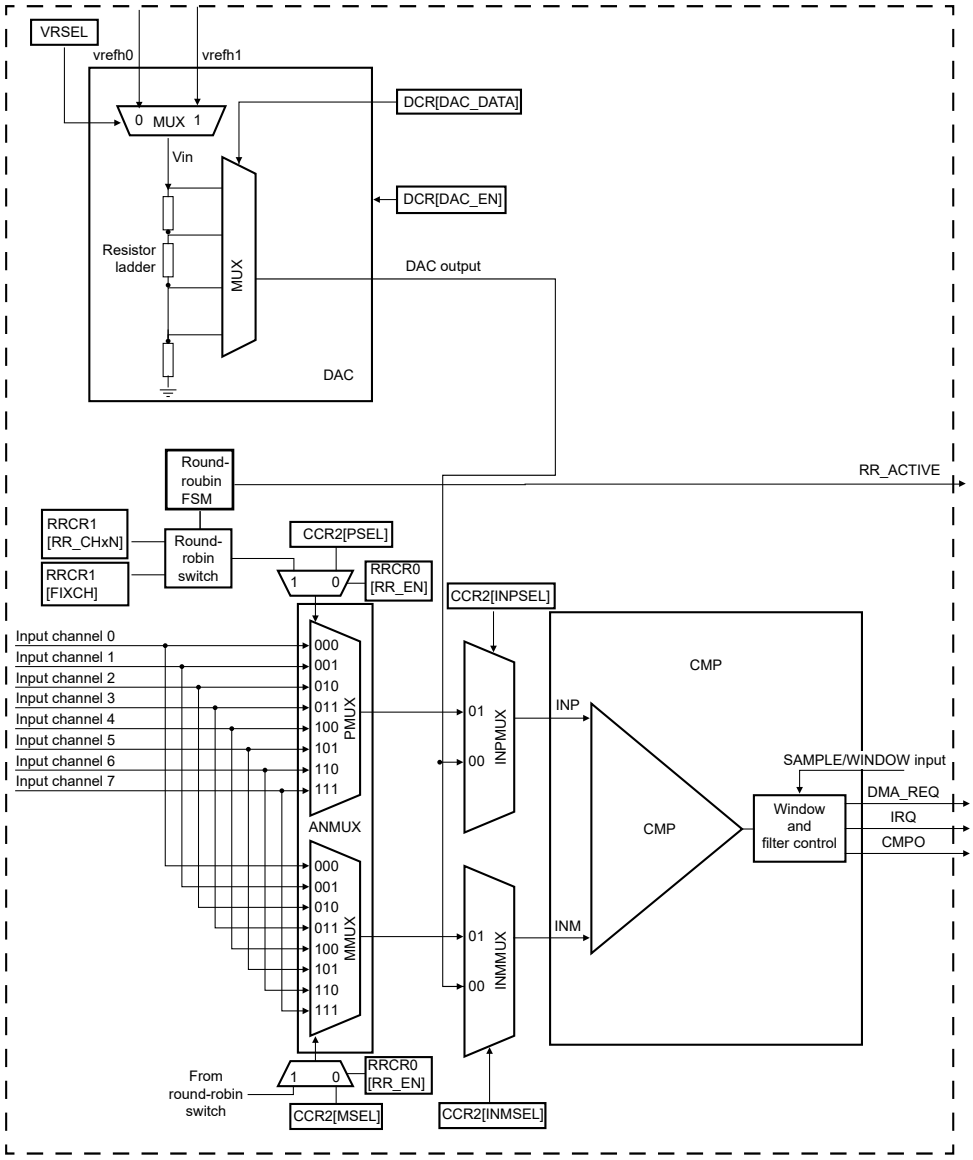

Figure 261. Block diagram

61.2.2 Features

The features of the LPCMP module include：

- Includes two 8-to-1 channel MUXes to select input signal from eight channels
- Supports multiple operation modes to produce a wide range of outputs such as:
  - — Sampled
  - — Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - — Digitally filtered
- Provides the following advance features for window and sample:

- Window and sample signals can be inverted.
- CMPO rising, falling or both edges closes the window.
- CMPO level can be defined when window is closed.

- Provides selectable performance levels:
  - Low-Power (speed) mode
  - High-Power (speed) mode
- Supports programmable hysteresis control
- Provides a selectable inversion on comparator output
- Uses an external hysteresis at the same time the output filter is used for internal functions
- Provides interrupt and DMA support
- Supports Round Robin Trigger mode
- Includes an 8-bit resolution DAC
- Provides a selectable supply reference source for DAC

61.3 Functional description

61.3.1 Functional block diagram

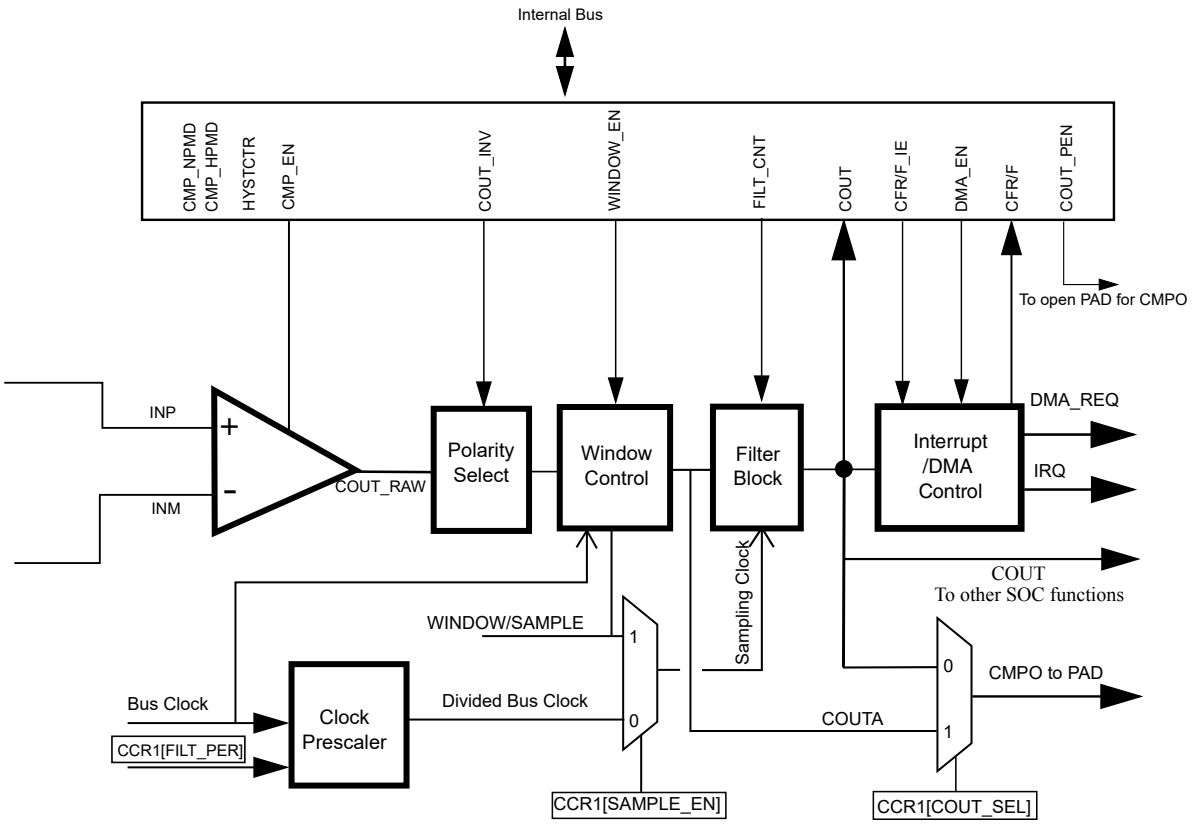

Figure 262. Functional block diagram

As shown in the block diagram, the functions are:

- Compared two analog input voltages applied to INP and INM, COUT_RAW is high when the INP input voltage is greater than the INM input voltage, and COUT_RAW is low when the INP input voltage is less than the INM input voltage.
- The COUT_RAW signal can be inverted by enabling CCR1[COUT_INV].
- The optionally inverted comparator output COUT_RAW is sampled on every bus clock when you enable the CCR1[WINDOW_EN] to generate COUTA. In this case, the comparator output is ignored during time periods when the input voltages are not valid. This is useful when you implement zero-crossing-detection for certain PWM applications.
- The window control block is bypassed when CCR1[WINDOW_EN] is disabled.
- The filter block acts as a simple sampler when CCR1[FILT_CNT] is set to 01h.
- The filter block acts as a filter based on multiple samples when CCR1[FILT_CNT] is set to be greater than 01h.
  - If CCR1[SAMPLE_EN] is set to 1, use the external SAMPLE input as the sampling clock.
  - If CCR1[SAMPLE_EN] is set to 0, use the divided bus clock as the sampling clock.
- Bypasses the filter block when it is not in use.

```
Bypass_Filter_Block = (FILT_CNT == 0x00) |  (~SAMPLE_EN & (FILT_PER == 0x00))
```

- Both COUTA and COUT can be configured as module output CMPO by configuring CCR1[COUT_SEL], and are used for different purposes within the system.
- The optionally filtered COUT can be read directly in CSR[COUT].
- The SAMPLE/WINDOW signal can be inverted by setting CCR1[WINDOW_INV].
- The SAMPLE/WINDOW signal can be closed by CMPO's falling edge and/or rising edge by setting CCR1[WINDOW_CLS] in Window mode.
- In Window mode, when window is closed, define the COUTA value as CCR1[COUTA_OW] by setting CCR1[COUTA_OWEN]. If CCR1[COUTA_OWEN] is not set, COUTA holds the last sampled value.

NOTE

See the chip configuration section for the source of SAMPLE/WINDOW input.

61.3.2 Round-robin trigger mode

You can enable Round-Robin Trigger mode by setting RRCR0[RR_EN] and CCR0[CMP_EN] to 1. A trigger event initiates a comparison sequence. The next trigger event should not occur before the current sequence completes.

RRCR1[FIXP] and RRCR1[FIXCH] select the reference channel for the plus side mux or the minus side mux. RRCR1[RR_CHnEN] selects active channels.

When a trigger comes, the analog comparator enables. After the comparison sequence completes, the analog comparator disables again. RRCR0[RR_INITMOD] controls the analog stabilization time.

NOTE

RR_INITMOD*round robin clock period must be longer than the initialization delay specified in the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet.

After the stabilization process completes, the round robin manner comparison sequence begins. Sample the comparison result for the selected active channel after RRCR0[RR_NSAM] defines the configurable number of operation clocks.

After all the active channels are sampled/compared, if the comparison result changes from its pre-programmed state, the corresponding flag in RRSR[RR_CHnF] is set. Write to RRCSR[RR_CHnOUT] to configure the pre-programmed state for each channel. Update RRCSR[RR_CHnOUT] to store the last comparison result for each channel. If any flag in RRSR[RR_CHnF] sets, CSR[RRF] also sets. If IER[RRF_IE] sets, an asynchronous interrupt asserts. Note that these flags do not support generating a DMA transfer event.

The following diagram shows the basic flow of this mode. In the diagram, RRCR1[RR_CH1EN], RRCR1[RR_CH3EN], and RRCR1[RR_CH4EN] are 1, so channels #1, #3, and #4 are selected for round-robin depending on their priority setting. RRCR0[RR_NSAM] sets to 2'b01, so you can sample one clock later the comparison result of the selected channel. After you compare the channel #4, the result is sampled, and round-robin ends. If any of the comparison results from channel #1, #3, or #4 changed from their programmed value (written to RRCSR[RR_CH1OUT], RRCSR[RR_CH3OUT], and RRCSR[RR_CH4OUT]), generates an interrupt. Software can then poll RRSR[RR_CHnF] to see which channel input(s) changed value.

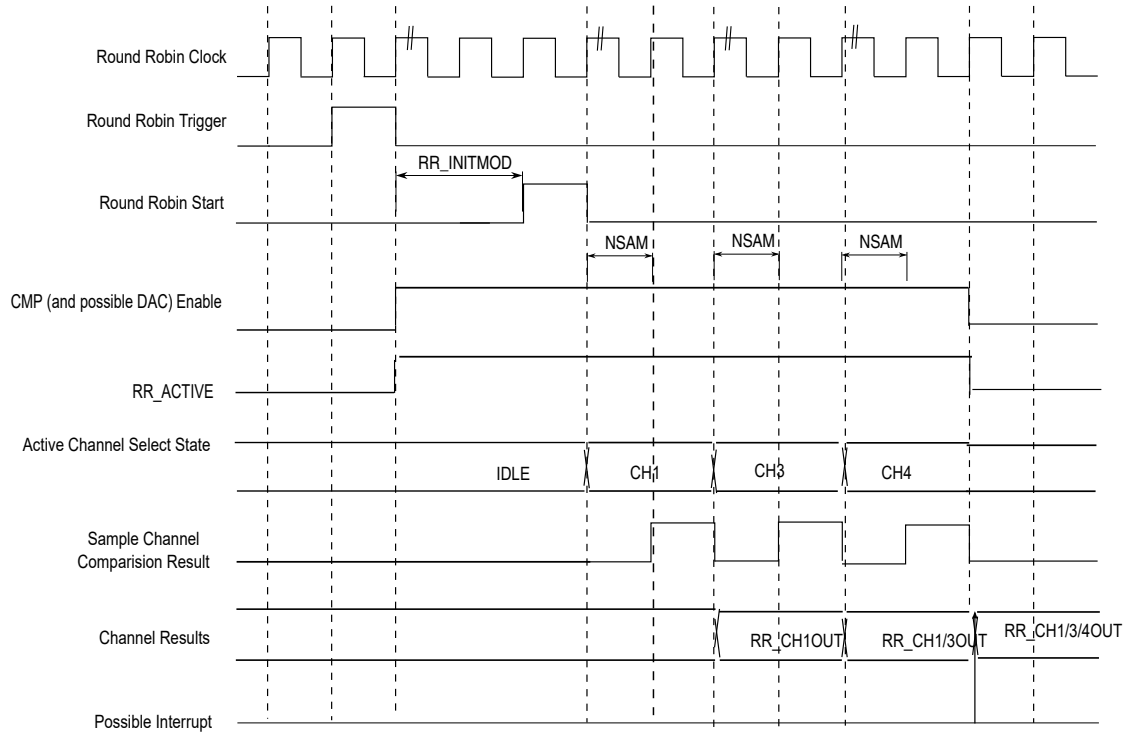

Figure 263. Trigger mode

The table below shows the channel decode in both Functional mode and Trigger mode. Other cases not in the table are illegal.

Table 350. CMP channel decode in functional mode and round-robin trigger mode

Mode	RR_EN	PSEL[2:0]	MSEL[2:0]	INPSEL[1:0]	INMSEL[1:0]	FIXP	FIXCH[2:0]	RR_CHxN	INP	INM	CMP Behavior
Functional mode	0	x[1]	0 to 7	0	1	x	x	x	DAC	Channel decoded from MSEL[2:0]	Channel 0 to 7 can be compared with DAC

Table continues on the next page...

Table 350. CMP channel decode in functional mode and round-robin trigger mode (continued)

Mode	RR_EN	PSEL[2:0]	MSEL[2:0]	INPSEL[1:0]	INMSEL[1:0]	FIXP	FIXCH[2:0]	RR_CHxN	INP	INM	CMP Behavior
		0 to 7	x	1	0	x	x	x	Channel decoded from PSEL[2:0]	DAC	Channel 0 to 7 can be compared with DAC
		0 to 7	0 to 7	1	1	x	x	x	Channel decoded from PSEL[2:0]	Channel decoded from MSEL[2:0]	Channel 0 to 7 can be compared with channel 0 to 7[2]
Trigger mode	1	x	x	0	1	0	x	0 to 7	DAC	Channel sweep (RR_CHxN)	Channel 0 to 7 can be swept with DAC
		x	x	1	0	1	x	0 to 7	Channel sweep (RR_CHxN)	DAC	Channel 0 to 7 can be swept with DAC
		x	x	1	1	0	0 to 7	0 to 7	Channel fixed by FIXCH[2:0]	Channel sweep (RR_CHxN)	Channel 0 to 7 can be swept with a fixed channel(0 to 7)[3]
		x	x	1	1	1	0 to 7	0 to 7	Channel sweep (RR_CHxN)	Channel fixed by FIXCH[2:0]	Channel 0 to 7 can be swept with a fixed channel(0 to 7)[3]

1. "x" means "don't care"
2. PSEL should not be same as MSEL.
3. Channel in the sweep side should not be same as the fixed side.

61.3.3 Low-pass filter mode

The low-pass filter mode operates on an unfiltered, optionally inverted comparator output COUTA, and generates the filtered and synchronized output COUT. You can configure both COUTA and COUT as module outputs and use for different purposes within the system.

Synchronization and edge detection determine the bit values of status register. They also apply to COUT for all sampling and windowed modes. You can perform filtering using an internal timebase defined by CCR1[FILT_PER], or use an external sample input to determine sample time.

The need for digital filtering and the amount of filtering depends on your requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, generate a high-frequency oscillations at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

61.3.3.1 Enabling low-pass filter mode

You can enable low-pass filter mode by setting the following:

- CCR1[FILT_CNT] > 01h
- CCR1[FILT_PER] to a nonzero value or writing 1 to CCR1[SAMPLE_EN].

If you use the divided bus clock to drive the low-pass filter, it samples COUTA every CCR1[FILT_PER] bus clock cycle.

If CCR1[SAMPLE_EN] is set to 1, the low-pass filter samples COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CCR1[FILT_CNT] samples agree that the output value has changed.

61.3.3.2 Latency issues

Program the value of CCR1[FILT_PER] or sample period such that the sampling period is longer than the period of the expected noise, ensuring that a given noise spike corrupts only one sample. You must choose the value of CCR1[FILT_CNT] to reduce the probability of noisy samples causing an incorrect transition to recognize. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CCR1[FILT_CNT].

You must trade off the values of CCR1[FILT_PER] or sample period and CCR1[FILT_CNT] against the need for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CCR1[FILT_CNT].

Table 352 summarizes maximum latency values for the various modes of operation in the absence of noise. Filtering latency restarts each time the noise masks an actual output transition.

61.3.4 Low power mode operation

Below table introduces the mode of operation of lower power.

Table 351. Low power mode operation

Mode of operation	Description
STOP	LPCMP can operate only in Continuous mode or Round-robin trigger mode.

61.3.5 Functional modes

You can combine the comparator window and filter features as shown in the following table.

Table 352. Functional modes

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
1	0	X	X	X	X	See the Disabled mode (#1).	N/A
2A	1	0	X	0x00	X	See the Continuous mode (#2A and #2B).	T_{PD}
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	See the Sampled, non-filtered mode (#3A and #3B).	$T_{PD} + T_{SAMPLE} + 3T_{per}$
3B	1	0	0	0x01	> 0x00		$T_{PD} + (FILT\_PER * T_{per}) + 3T_{per}$

Table continues on the next page...

Table 352. Functional modes (continued)

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
4A	1	0	1	> 0x01	X	See the Sampled, filtered mode (#4A and #4B).	T_{PD} + (FILT_CNT * T_{SAMPLE}) + $3T_{per}$
4B	1	0	0	> 0x01	> 0x00		T_{PD} + (FILT_CNT * FILT_PER x T_{per}) + $3T_{per}$
5A	1	1	0	0x00	X	See the Windowed mode (#5A and #5B).	T_{PD} + $2T_{per}$
5B	1	1	0	X	0x00		
6	1	1	0	0x01	> 0x00	See the Windowed/ Resampled mode (#6).	T_{PD} + (FILT_PER * T_{per}) + $3T_{per}$
7	1	1	0	> 0x01	> 0x00	See the Windowed/ Filtered mode (#7).	T_{PD} + (FILT_CNT * FILT_PER x T_{per}) + $3T_{per}$
All other combinations of CMP_EN, WINDOW_EN, SAMPLE_EN, FILT_CNT, and FILT_PER are illegal.							

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the bus clock.

61.3.5.1 Disabled mode (#1)

In this mode:

- The analog comparator is non-functional and consumes no power.
- CSR[COUT] and CMPO are the same as CCR1[COUT_INV].

61.3.5.2 Continuous mode (#2A and #2B)

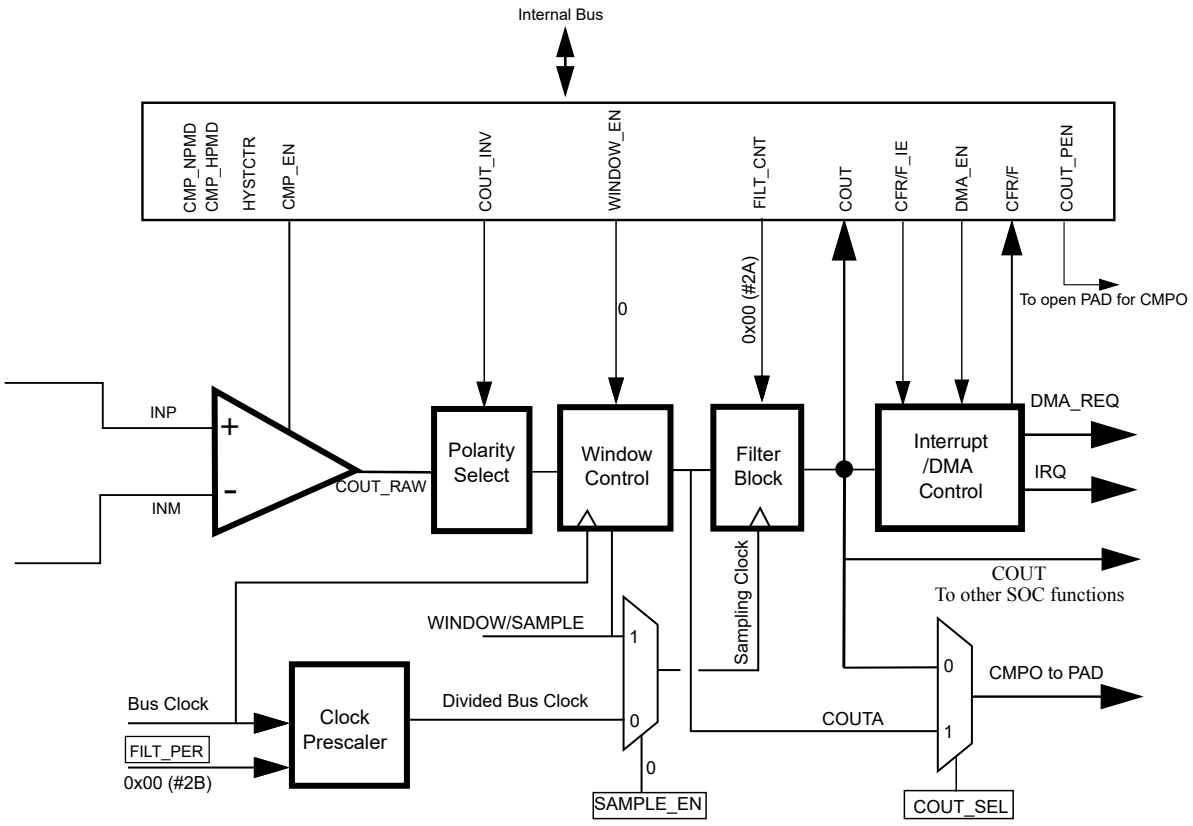

Figure 264. Comparator operation in continuous mode

COUT_RAW is optionally inverted in this mode but is not subject to external sampling or filtering. Both window control and filter blocks bypass completely, and CSR[COUT] updates continuously. The path from comparator input pins to output pins operates in a combinational (unclocked) mode. COUT and COUTA are identical in this mode.

For cases where a comparator drives a fault input, you must configure it to operate in Continuous mode so that an external fault can immediately pass to the target fault circuitry through the comparator.

61.3.5.3 Sampled, non-filtered mode (#3A and #3B)

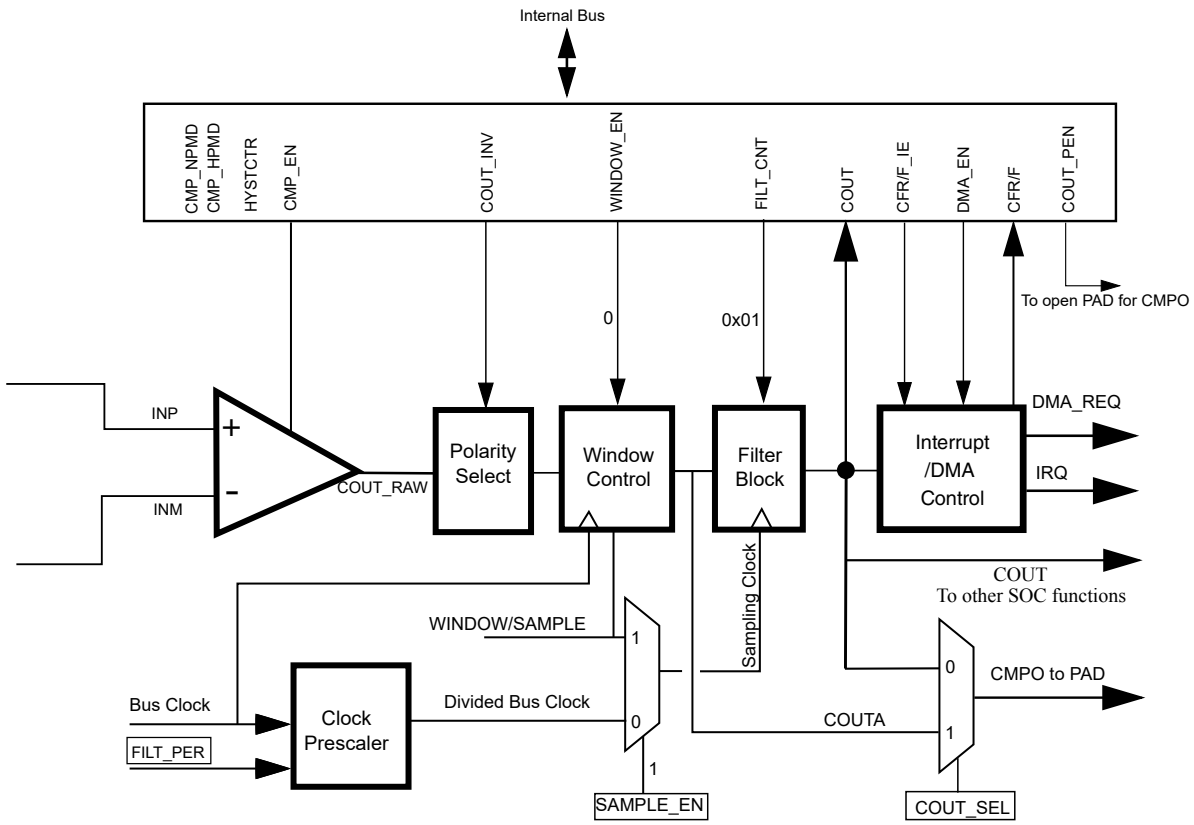

Figure 265. Sampled, non-filtered (#3A): sampling point externally driven

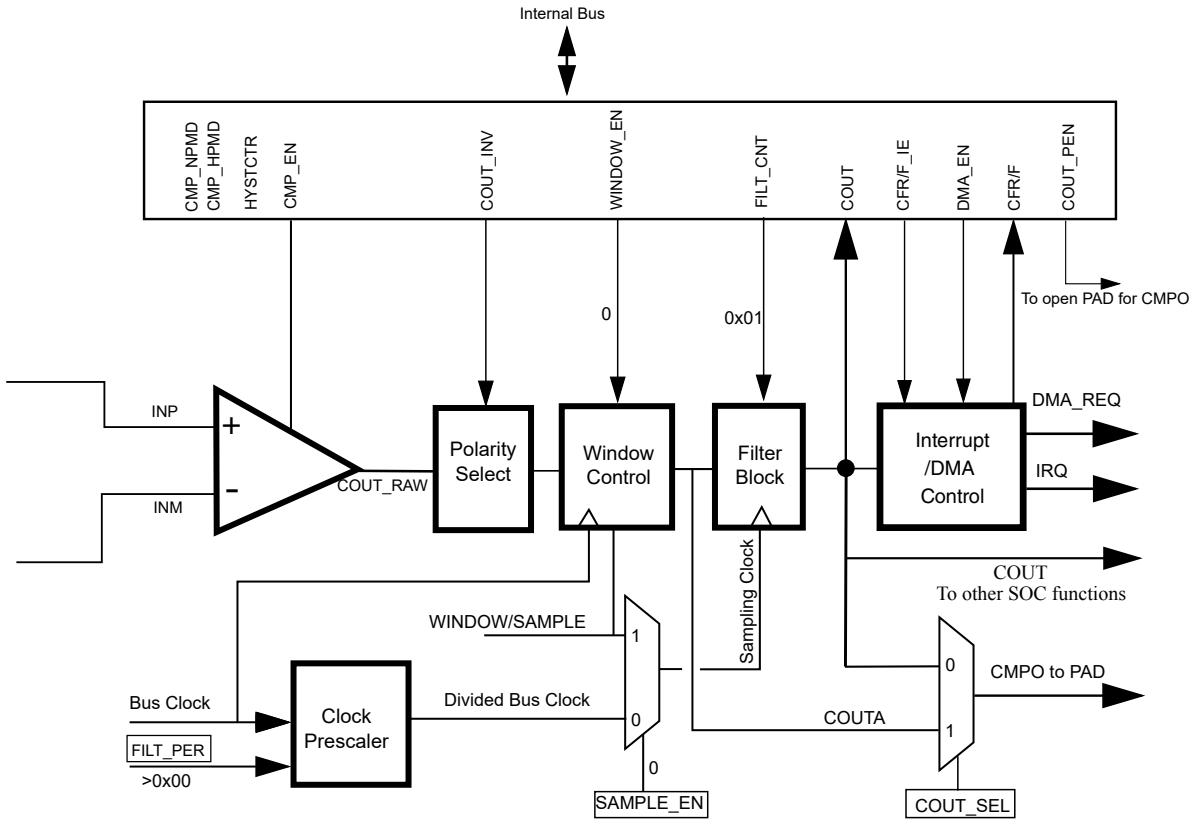

Figure 266. Sampled, Non-Filtered (#3B): sampling interval internally derived

In this mode, the path from analog inputs to COUTA is combinational (unclocked). Windowing control bypasses completely. You can sample COUTA whenever you detect a rising edge on the sampling clock.

The difference in two operation modes (#3A and #3B) of sampled, non-filtered mode is that how you drive the clock to the filter block. In #3A, the clock to filter block drives externally, and in #3B, the clock to filter block drives internally.

The filter block has no other function than sample or hold of the comparator output in this mode.

The following figure shows the comparator operation in this mode, assuming that the polarity select sets to a non-inverting state.

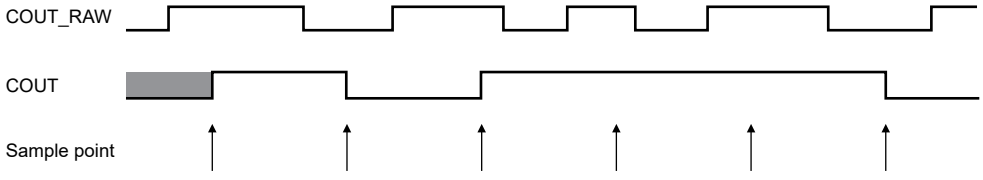

Figure 267. Sampled, Non-Filtered mode timing diagram

61.3.5.4 Sampled, filtered mode (#4A and #4B)

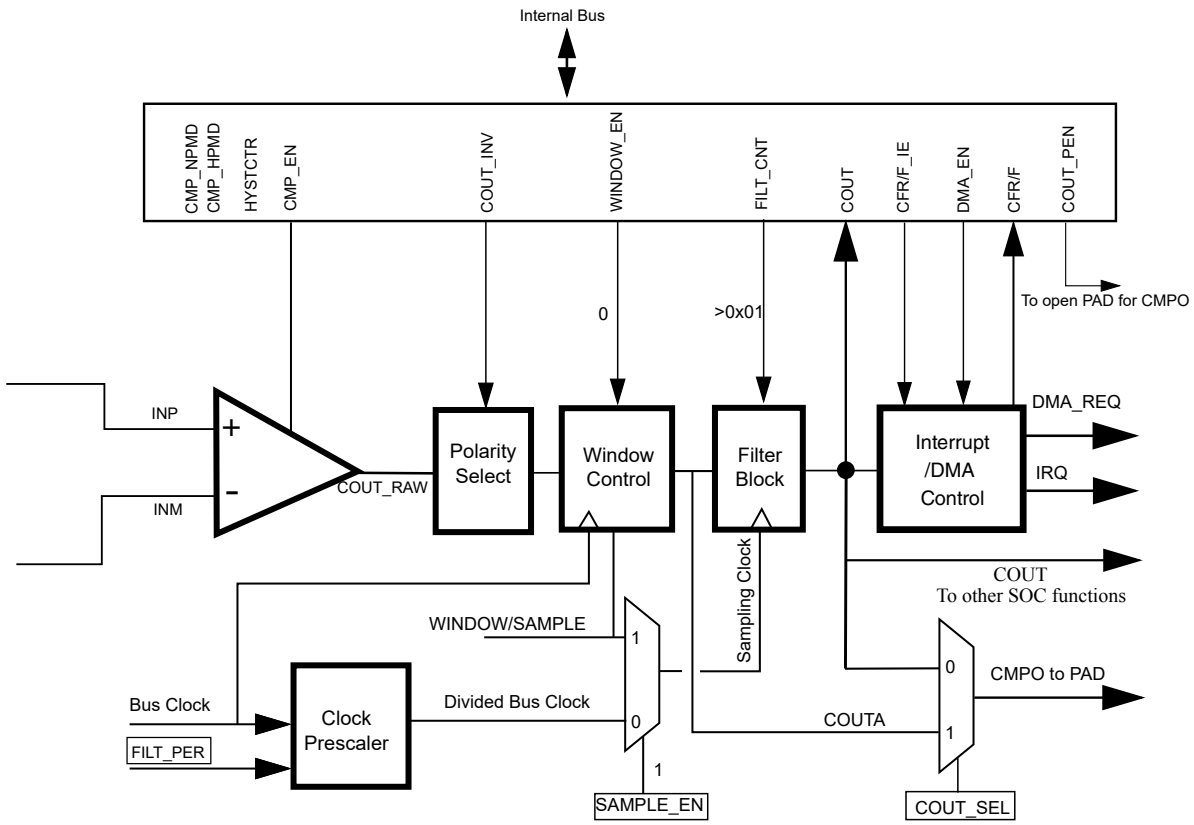

Figure 268. Sampled, filtered (#4A): sampling point externally driven

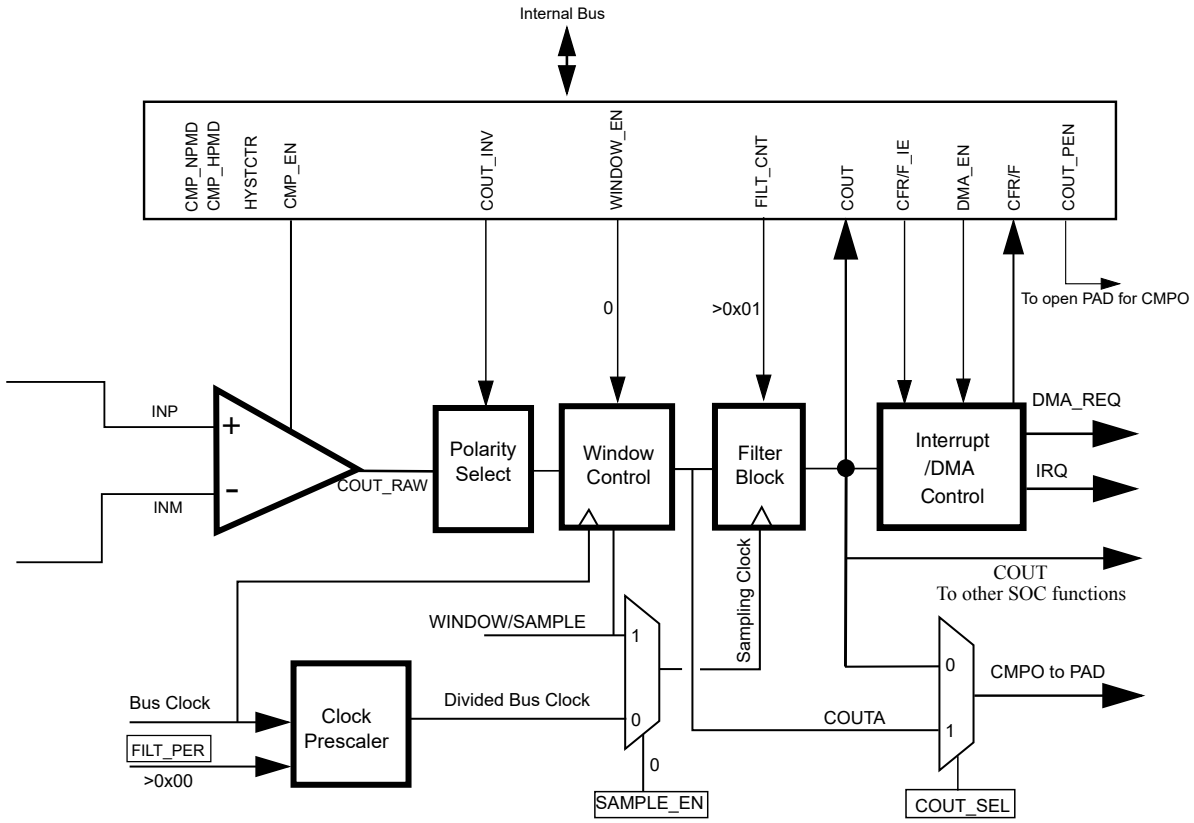

Figure 269. Sampled, filtered (#4B): sampling point internally derived

In this mode, the path from the analog inputs to COUTA is combinational(unclocked). Windowing control bypasses completely. You can sample COUTA whenever you detect a rising edge on the sampling clock.

The only difference in operation between sampled, non-filtered (#3A) mode and sampled, filtered (#4A) mode is that CCR1[FILT_CNT] is larger than 1, which activates filter operation.

The only difference in operation between sampled, non-filtered (#3B) mode and sampled, filtered (#4B) mode is that CCR1[FILT_CNT] is larger than 1, which activates filter operation.

61.3.5.5 Windowed mode (#5A and #5B)

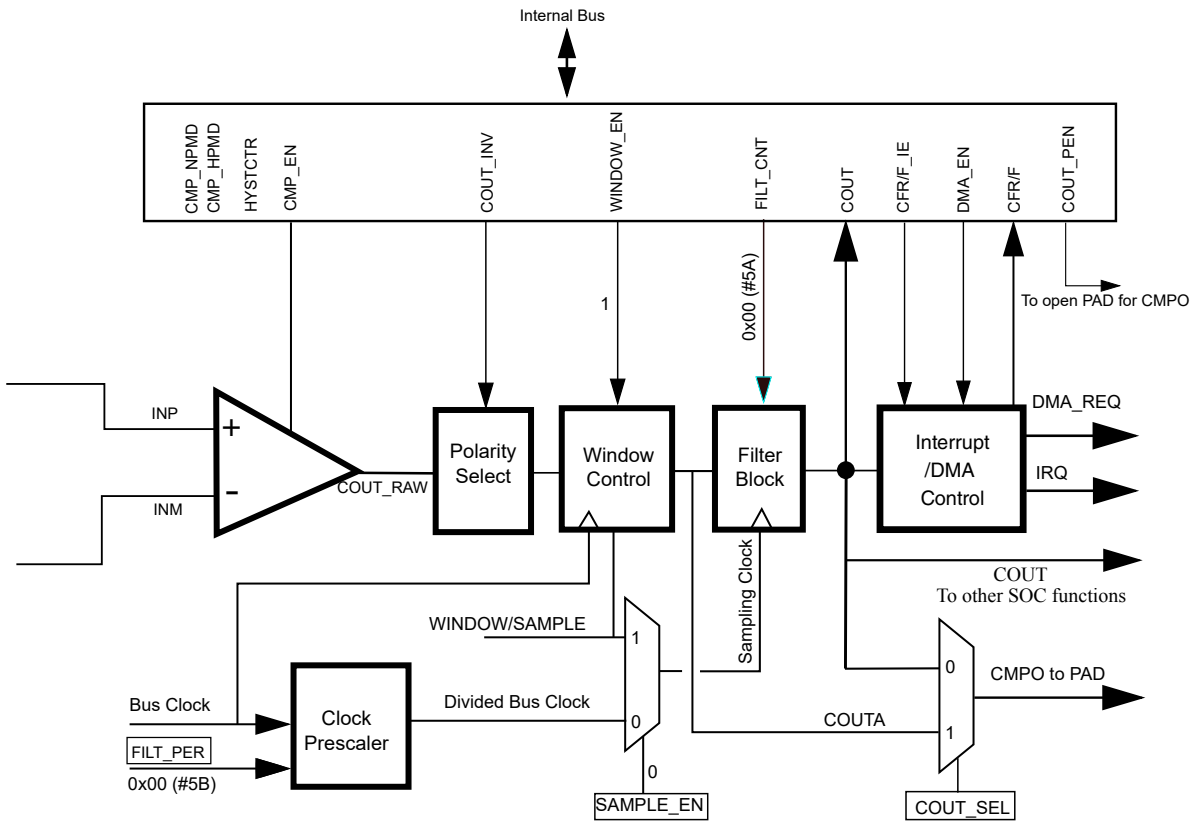

Figure 270. Windowed mode

The bus clock clocks COUTA whenever you enable the window in this mode. The last latched value holds after you disable the window and the filter block is bypassed.

The following figure shows the comparator operation in this mode, ignoring the latency of the analog comparator, polarity select, and window control block. The polarity select sets to a non-inverting state.

COUTA may lag the analog inputs by up to two functional clock cycles plus the combinational path delay through the comparator and polarity select logic in the actual operation.

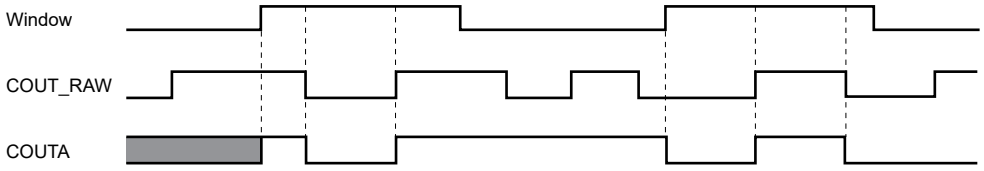

Figure 271. Windowed mode timing diagram

The following figure shows that if CCR1[COUTA_OWEN] becomes 1, you can define COUTA level as CCR1[COUTA_OW], after you closes the window.

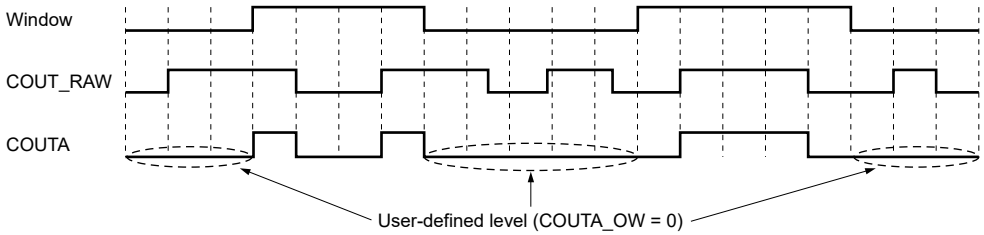

Figure 272. Windowed mode timing diagram with user defined value 0 outside window

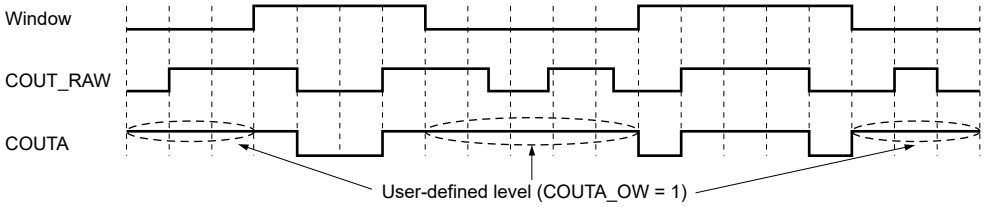

Figure 273. Windowed mode timing diagram with user defined value 1 outside window

NOTE

When the window is open, COUT_A will switch from COUTA_OW to COUT_RAW. When the window is closed, COUT_A will switch from COUT_RAW to COUTA_OW. This may generate unnecessary transition flags, for instance, CFR or CFF. User needs to choose COUTA_OW carefully according to the actual application, and select the appropriate flag CFR or CFF to generate interrupt.

If CCR1[WINDOW_CLS] becomes 1, you can define the CMPO event (rising edge, falling edge or both edges that CCR1[EVT_SEL] selects) to close the window. The external window signal has to go to zero and back to one to enable the internal window again. The following figure shows an example that CMPO rising edge closes the internal window.

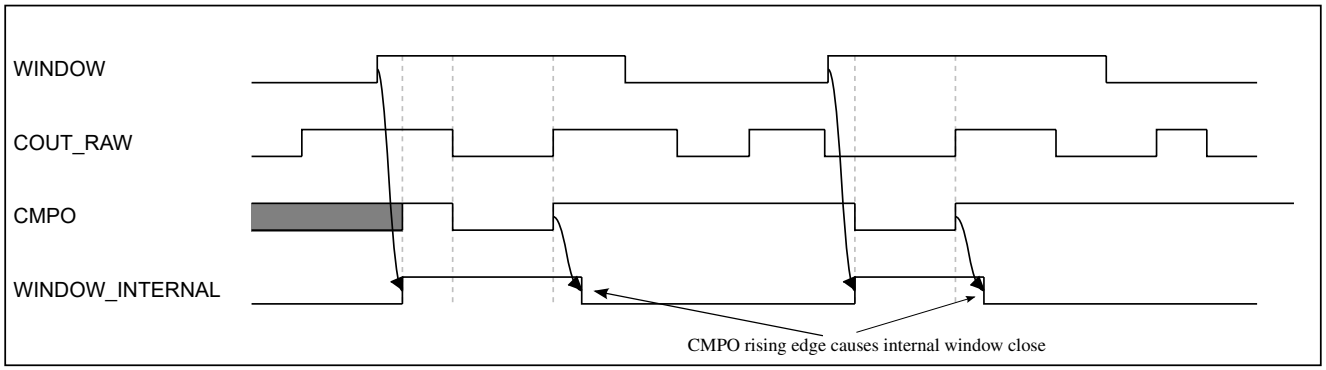

Figure 274. Windowed mode timing diagram with CMPO rising edge close window

The following figure shows that if CCR1[WINDOW_INV] becomes 1, you can invert the window signal before you use it.

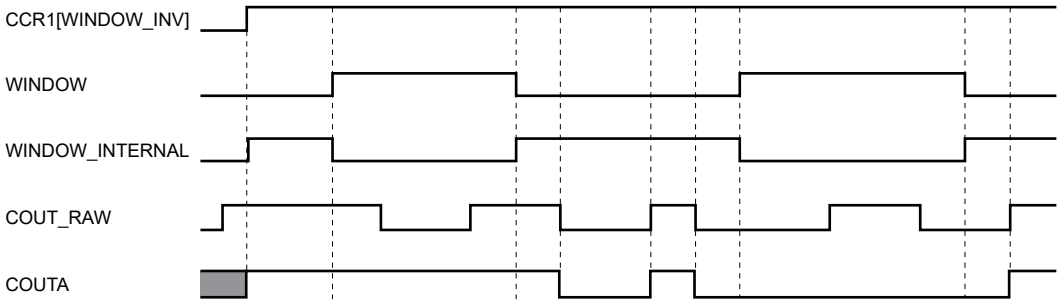

Figure 275. Windowed mode timing diagram with window signal inverted

61.3.5.6 Windowed/Resampled mode (#6)

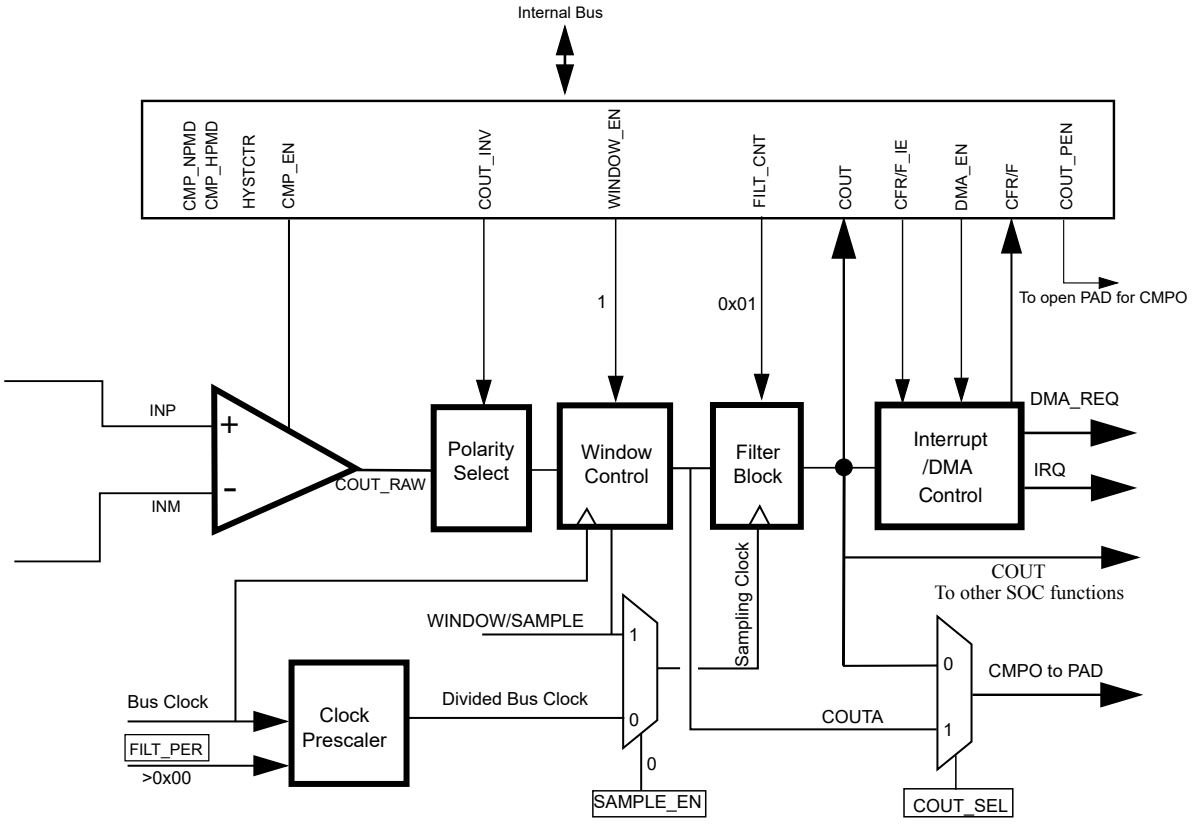

Figure 276. Windowed/Resampled mode

This mode of operation results in an unfiltered string of comparator samples where CCR1[FILT_PER] and the bus clock rate determines the interval between the samples. The following section shows that the configuration for this mode is virtually identical to that for the Windowed/Filtered mode. The only difference is that the value of CCR1[FILT_CNT] must be 1 in this mode.

The following figure uses the same input stimulus shown in Figure 271, and adds resampling of COUTA to generate COUT. The arrows in the figure indicate the time points at which the samples are taken. You can ignore prop delays and latency for clarity.

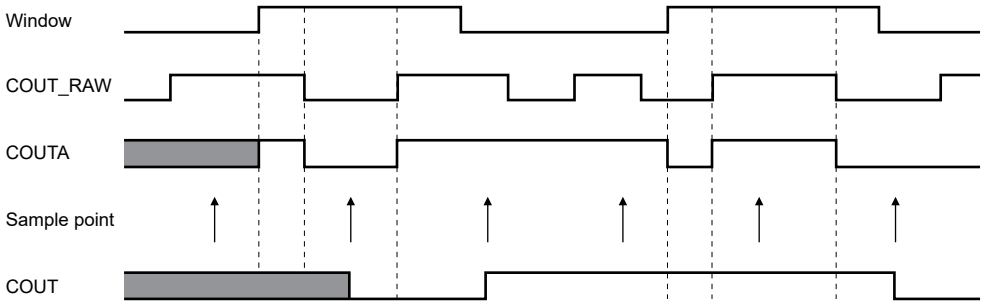

Figure 277. Windowed/Resampled mode operation

This example demonstrates the operation of the comparator in Windowed/Resampled mode, and does not reflect any specific application. Based on the sampling rate and window placement, COUT may not see zero-crossing events that the analog comparator detects. You must carefully consider the sampling period and/or window placement for a given application.

61.3.5.7 Windowed/Filtered mode (#7)

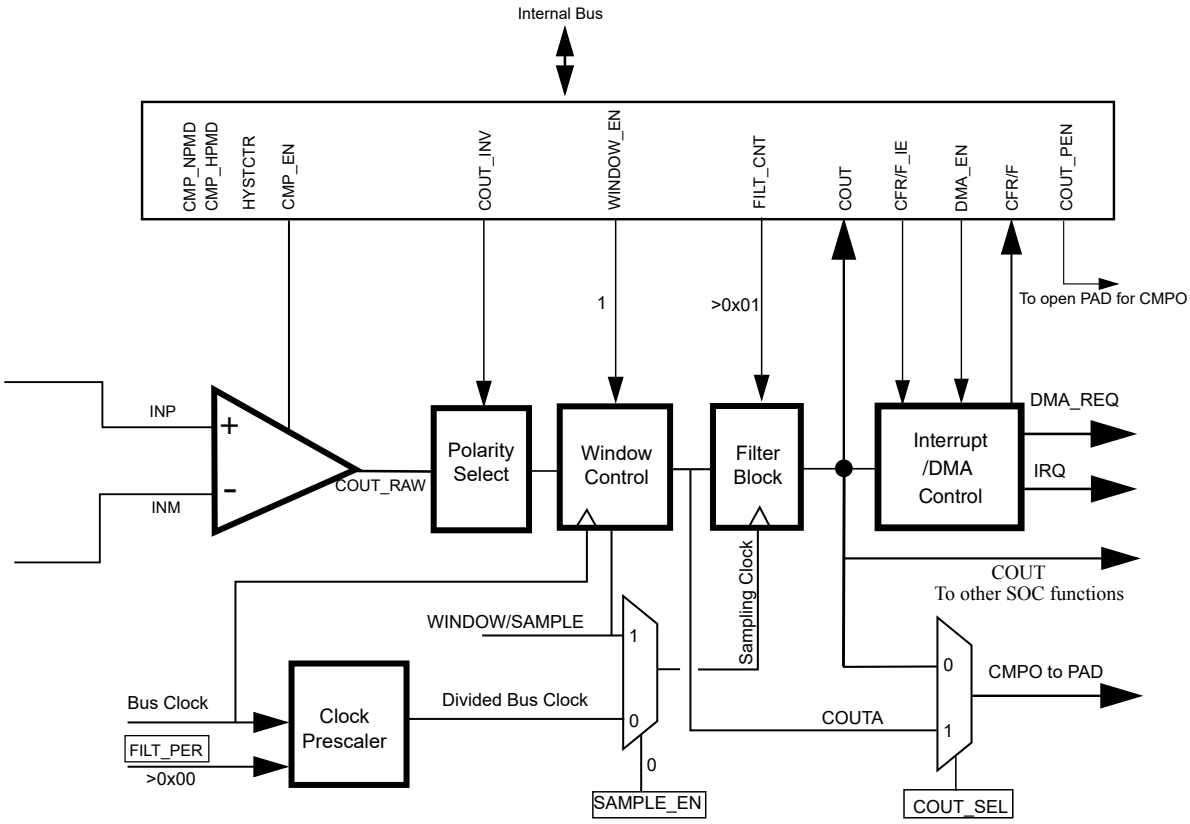

Figure 278. Windowed/Filtered mode

The only difference in operation between Windowed/Resampled mode (#6) and Windowed/Filtered mode (#7) is that CCR1[FILT_CNT] is >1, which activates filter operation.

This mode is the most complex mode of operation for the comparator block, as it utilizes both windowing and filtering features. It also has the highest latency of any of the modes. This is approximately: up to 2 peripheral clock synchronization in the window function + ((CCR1[FILT_CNT] x CCR1[FILT_PER]) + 1) x peripheral clock for the filter function.

61.3.6 DMA

After DMA is enabled by writing 1 to CCR1[DMA_EN] and interrupt is enabled by writing 1 to IER[CFR_IE], IER[CFF_IE], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt. After the DMA completes the transfer, it sends a transfer completing indicator signal that deasserts the DMA transfer request and clears the flags (both CSR[CFR] and CSR[CFF]) to allow a subsequent change on comparator output to occur and forces another DMA request.

61.3.7 Clocking

LPCMP requires the following clocks to operate:

Table 353. LPCMP clocks

Type of clock	Description
Bus	Controls the access to LPCMP registers and window/ filter function.
Round-robin clock (RCLK)	Controls Round-robin trigger mode.

61.3.8 Resets

The global chip reset signal resets LPCMP.

61.3.9 Interrupts

After the corresponding IER becomes 1, CSR[CFR], CSR[CFF], and CSR[RRF] can generate an interrupt, assuming that CCR1[DMA_EN] is not 1. You can clear either the flag or IER to deassert the interrupt.

61.4 External signal descriptions

Below table introduces external signals.

Table 354. External signal descriptions

Signal	Description	I/O
CMPO	Filtered or unfiltered comparator output	O
Input_Analog_Channels	Analog input channels (see the chip-specific information for more on the connections).	I
VREFH_EXT	External reference voltage for the CMP-DAC (see the chip-specific information for more on the connections).	I
RR_ACTIVE	Round-robin trigger mode enabled.	O

61.5 Initialization

You can enable LPCMP by writing 1 to CCR0[CMP_EN], and then configuring the control registers (CCR1, CCR2, DCR, and so on).

To disable LPCMP, write 0 to CCR0[CMP_EN]. Switching operation modes or changing control register fields on-the-fly (when CCR0[CMP_EN] is set to 1) may cause noise on the COUT or COUTA signals. To avoid unwanted signal noise, you must ensure to disable the module before switching modes or changing control fields.

The time required to stabilize COUT is the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter (see the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet for more information on propagation delay and power-up delay). Table 352 specifies the delay that the windowing and filter function causes.

During operation, you must always consider the propagation delay of the selected data paths. It can take many bus clock cycles for COUT and CSR[CFR]/CSR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

61.6 Application information

61.6.1 Round-robin trigger mode programing recommendation

Configure the Round-robin trigger mode as follows:

1. Configure the comparison cycles by RRCR0[RR_NSAM]. Note: It is a mandatory request that the round robin cycling period must set longer than the time that all the active channels complete the specified comparison cycles set by RRCR0[RR_NSAM].
2. Configure CMP initialization delay by RRCR0[RR_INITMOD]. Note: In programming RRCR0[RR_INITMOD], the RR_INITMOD x round robin clock period must be longer than the initialization delay, see the LPCMP datasheet for more information.
3. Configure RRCR1[FIXP] to select the fixed port of CMP and
    a. If you use one input channel to compare with other channels, configure RRCR1[FIXCH] to select the fixed channel.
    b. If you use DAC output to compare with input channels, configure CCR2[INPSEL] or CCR2[INMSEL] (according to RRCR1[FIXP]) to select the DAC output.
4. Configure channels for comparison by RRCR1[RR_CHnEN].
5. Write RRCSR[RR_CHnOUT] to define the pre-set state of channel n.
6. Clear channel flags RRSR[RR_CHnF].
7. Enable round robin interrupt by IER[RRF_IE] (disable IER[CFR_IE] and IER[CFF_IE]).
8. Enable round-robin trigger mode by setting RRCR0[RR_EN] to 1.
9. Enable comparator by setting CCR0[CMP_EN] to 1.

61.6.2 Round-robin clock (RCLK) frequency requirement

(1) RCLK high frequency limit

RCLK high frequency limit depends on two facts:

1. The analog CMP and DAC initialization time (see the chip data sheet for more information on the initialization time.)
    - RRCR0[RR_INITMOD] provides a maximum 63 RCLK cycles for the analog CMP and DAC initialization.
    - RCLK must be slow to assure: 63 * ($1/f_{RCLK}$) > $T_{initialization}$, where f_{RCLK} is in MHz, and $T_{initialization}$ is in microsecond.
    - so $f_{RCLK} < 63 / T_{initialization}$
    - Example: $T_{initialization}$ = 40 µs, then f_{RCLK} should be smaller than 1.575 MHz.
2. The analog CMP propagation delay (see the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet for more information on the CMP propagation delay.)
    - RRCR0[RR_NSAM] provides a maximum 4 RCLK cycles for the analog CMP propagation delay.
    - RCLK must be slow to assure: 4 * ($1/f_{RCLK}$) > $T_{propagation}$, where f_{RCLK} is in MHz, and $T_{propagation}$ is in microsecond.
    - $f_{RCLK} < 4 / T_{propagation}$
    - Example: $T_{propagation}$ = 0.1 µs, then f_{RCLK} must be smaller than 40 MHz.

(2) RCLK low frequency limit

In theory, RCLK frequency has no low limit. But the lower the RCLK frequency, the longer the scan time. Therefore, the lower limit of the RCLK frequency depends on the system application.

61.7 LPCMP register descriptions

The memory map comprises of 32-bit aligned registers, which you can access via 8-, 16- or 32-bit reads and 32-bit write. Attempted accesses using unsupported write data sizes, writes to read-only resources, or to reserved spaces terminate with an error. Read access to reserved address generates a transfer error and the read data bus shows all 0s.

61.7.1 LPCMP memory map

LPCMP_0 base address: 4037_0000h

LPCMP_1 base address: 4037_4000h

LPCMP_2 base address: 404E_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VERID)	32	R	0100_0001h

30h	Round Robin Status (RRSR)	32	RW	0000_0000h

61.7.2 Version ID (VERID)

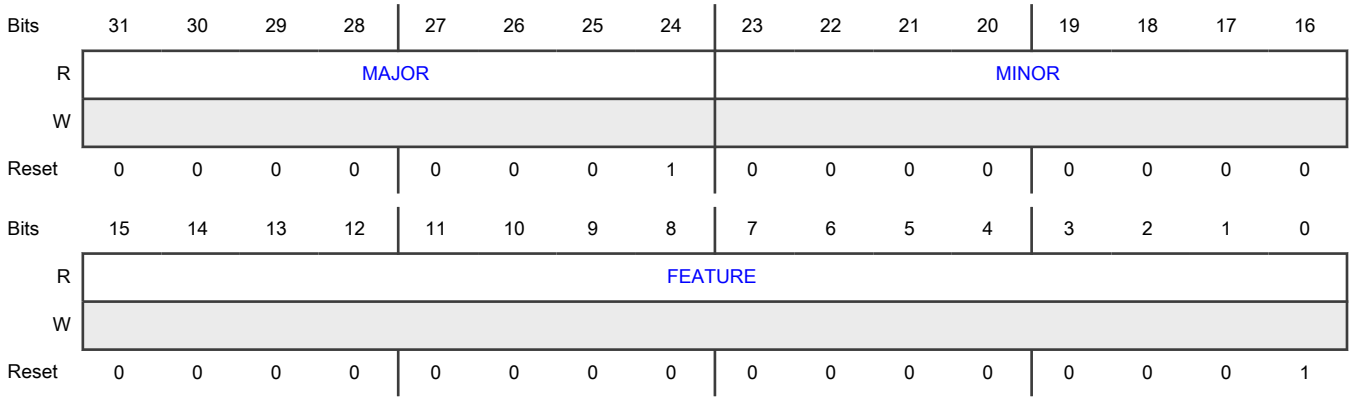
Offset

Register	Offset
VERID	0h

Function

Contains version numbers for the module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module design.
23-16 MINOR	Minor Version Number Returns the minor version number for the module design.
15-0 FEATURE	Feature Specification Number Returns the feature set number. 0000_0000_0000_0001b - Round robin feature

61.7.3 Parameter (PARAM)

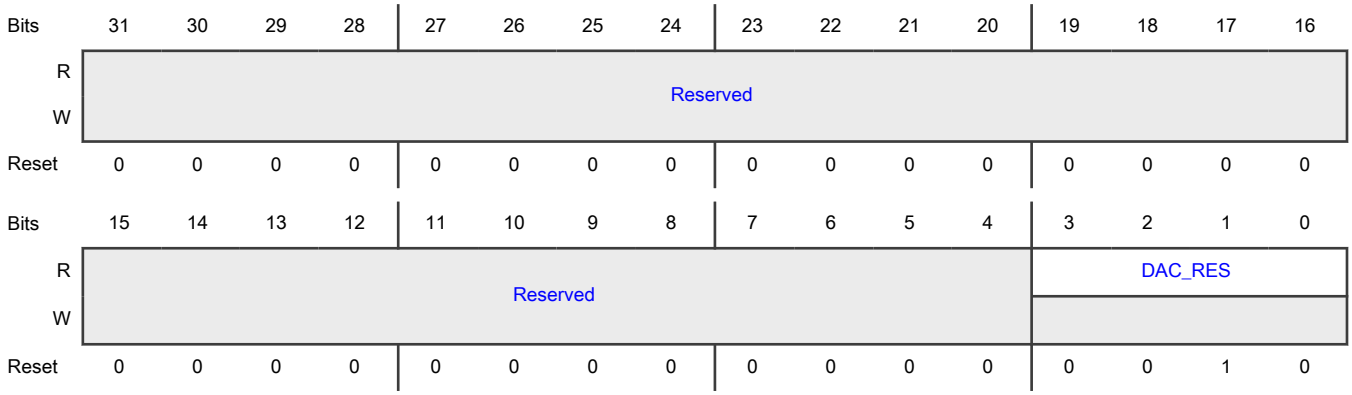
Offset

Register	Offset
PARAM	4h

Function

Contains parameter values that are implemented in the module.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 DAC_RES	DAC Resolution Indicates supported DAC resolutions. **NOTE** All other bit field values are reserved. 0000b - 4-bit DAC 0001b - 6-bit DAC 0010b - 8-bit DAC 0011b - 10-bit DAC 0100b - 12-bit DAC 0101b - 14-bit DAC 0110b - 16-bit DAC

61.7.4 Comparator Control Register 0 (CCR0)

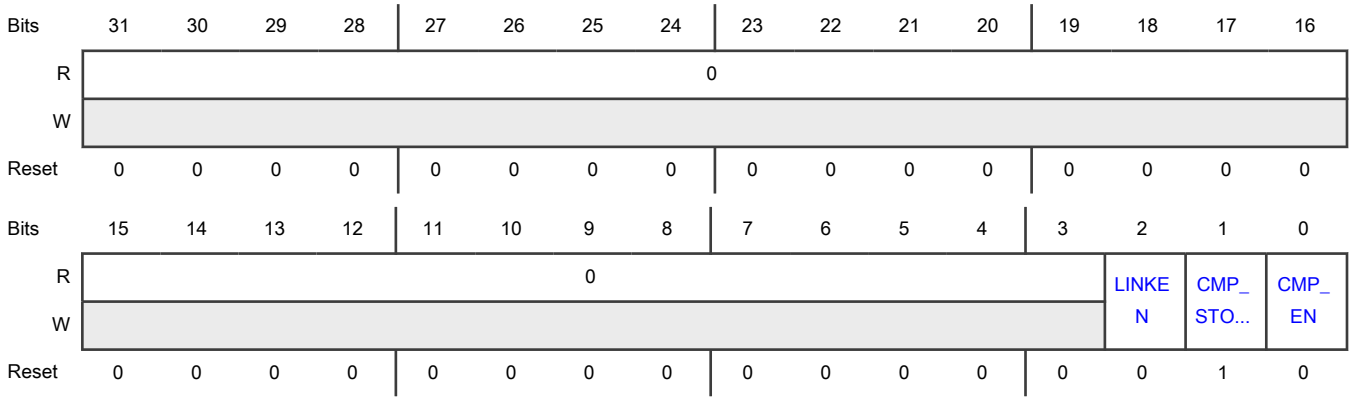
Offset

Register	Offset
CCR0	8h

Function

Contains configuration options for enabling the analog comparator and the DAC.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 LINKEN	CMP-to-DAC Link Enable Enables the CMP-to-DAC link. 0b - Disable: enabling or disabling the DAC is independent from enabling or disabling the CMP. 1b - Enable: enabling/disabling DAC is controlled by the CMP_EN bit instead of DCR[DAC_EN]. Also, when the CMP is auto-disabled because software selects the same signal for both the plus and minus comparator inputs, the DAC is disabled too.
1 CMP_STOP_EN	Comparator STOP Mode Enable Enables the analog comparator or the DAC when the module is in STOP mode. **NOTE** This field has no effect in Round-robin Trigger mode. 0b - Disables the analog comparator regardless of CMP_EN. 1b - Allows CMP_EN to enable the analog comparator.
0 CMP_EN	Comparator Enable Enables the analog comparator. **NOTE** When CCR0[LINKEN]=1, CMP_EN also controls the enabling/disabling of the DAC instead of DCR[DAC_EN]. 0b - Disable (The analog logic remains off and consumes no power.) 1b - Enable

61.7.5 Comparator Control Register 1 (CCR1)

Offset

Register	Offset
CCR1	Ch

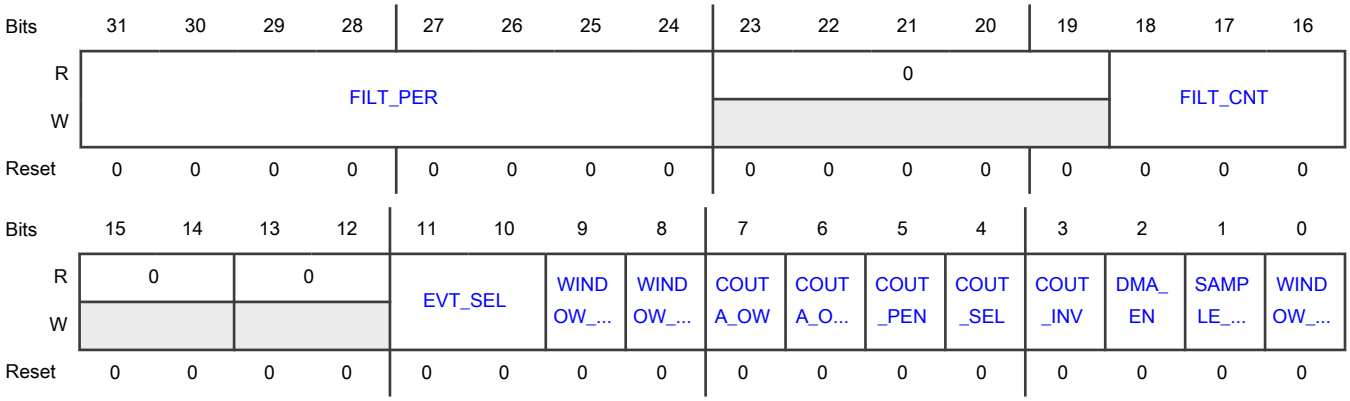
Function

Contains configuration options for the comparator operation, such as enabling Sampling or Windowing mode.

NOTE

You cannot enable Sampling and Windowing modes both at the same time. Sampling mode takes precedence over Windowing mode. If you write 1 to both SAMPLE_EN and WINDOW_EN, only SAMPLE_EN becomes 1.

Diagram



Fields

Field	Function
31-24 FILT_PER	Filter Sample Period Specifies the sampling period (in bus clock cycles) of the comparator output filter. Programming this field to 00h bypasses the filter. See Functional description for more information on filter programming and latency. **NOTE** FILT_PER has no effect in Sampling mode (CCR1[SAMPLE_EN] = 1).
23-19 —	Reserved
18-16 FILT_CNT	Filter Sample Count Specifies the number of consecutive samples that must agree before the comparator output filter accepts the sample as a new valid output state. See Functional description for more information on filter programming and latency.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - Filter is bypassed: COUT = COUTA 001b - 1 consecutive sample (Comparator output is simply sampled.) 010b - 2 consecutive samples 011b - 3 consecutive samples 100b - 4 consecutive samples 101b - 5 consecutive samples 110b - 6 consecutive samples 111b - 7 consecutive samples
15-14 —	Reserved
13-12 —	Reserved
11-10 EVT_SEL	CMPO Event Select Selects which CMPO signal edge (rising, falling, or both) defines a CMPO event. **NOTE** Valid only in Windowing mode. 00b - Rising edge 01b - Falling edge 1xb - Both edges
9 WINDOW_CLS	CMPO Event Window Close Enables a CMPO event (defined as a CMPO rising edge, falling edge, or both) to close an active window. See EVT_SEL to configure the CMPO event. **NOTE** The WINDOW signal has to go to zero and back to one again to re-activate the window. Valid only in Windowing mode. 0b - CMPO event cannot close the window 1b - CMPO event can close the window
8 WINDOW_INV	WINDOW/SAMPLE Signal Invert Inverts the window/sample signal. 0b - Do not invert 1b - Invert
7	COUTA Output Level for Closed Window

Table continues on the next page...

Table continued from the previous page...

Field	Function
COUTA_OW	Defines the COUTA signal value when the window is closed. **NOTE** Valid only in Windowing mode and when COUTA_OWEN=1. 0b - COUTA is 0 1b - COUTA is 1
6 COUTA_OWEN	COUTA_OW Enable Enables the COUTA signal value to be defined by COUTA_OW when the window is closed. **NOTE** Valid only in Windowing mode. 0b - COUTA holds the last sampled value. 1b - Enables the COUTA signal value to be defined by COUTA_OW.
5 COUT_PEN	Comparator Output Pin Enable Enables the comparator output to become an available signal option for a selected package pin. 0b - Not available 1b - Available
4 COUT_SEL	Comparator Output Select Selects which comparator output option, COUT or COUTA, to use for CMPO. 0b - Use COUT (filtered) 1b - Use COUTA (unfiltered)
3 COUT_INV	Comparator Invert Selects the polarity of the analog comparator function, affecting the value driven to the COUT output (on both the chip pin and as CSR[COUT]) when CCR0[CMP_EN] is 0. **NOTE** COUT_INV has no effect in Trigger mode. 0b - Do not invert 1b - Invert
2 DMA_EN	DMA Enable Enables DMA transfers triggered from the LPCMP module. After this field and the corresponding interrupt enable field becomes 1, a DMA request is asserted when CFR or CFF becomes 1. 0b - Disable 1b - Enable
1	Sampling Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
SAMPLE_EN	Enables Sampling mode. 0b - Disable 1b - Enable
0 WINDOW_EN	Windowing Enable Enables Windowing mode. **NOTE** Valid only when SAMPLE_EN = 0. 0b - Disable 1b - Enable

61.7.6 Comparator Control Register 2 (CCR2)

Offset

Register	Offset
CCR2	10h

Function

Contains the configuration options for the comparator operation, such as selecting the plus and minus comparator inputs and the hysteresis levels.

NOTE

When an inappropriate operation selects the same signal for both the plus and minus comparator inputs, the analog comparator automatically shuts down (regardless of CMP_EN) to prevent itself from becoming a noise generator.

23-16 DAC_DATA	DAC Output Voltage Select Selects the DAC output (DACO) voltage from one of 256 distinct levels by configuring the value of DAC_DATA. The DACO ranges from Vin/256 to Vin. **NOTE** DACO = (Vin/256) * (DAC_DATA + 1)
15-9 —	Reserved
8 VRSEL	DAC Reference High Voltage Source Select Selects the high voltage reference source for the Vin supply of the DAC's resistor ladder network. See the chip-specific LPCMP information for the source of vrefh0 and vrefh1. 0b - VREFH0 1b - VREFH1
7-2 —	Reserved
1 —	Reserved
0 DAC_EN	DAC Enable Enables the DAC. When disabled, power-down the DAC to conserve power. **NOTE** You can control the link from the CMP enable to the DAC enable by setting up CCR0[LINKEN]. 0b - Disable 1b - Enable

61.7.8 Interrupt Enable (IER)

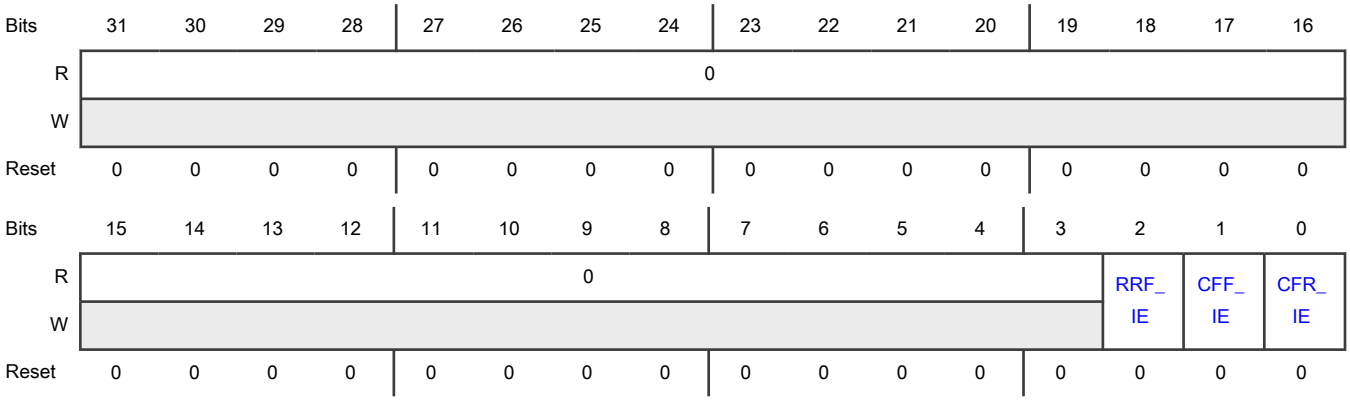
Offset

Register	Offset
IER	1Ch

Function

Provides enable fields for the comparator and round-robin flag interrupts.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 RRF_IE	Round-Robin Flag Interrupt Enable Enables or disables the round-robin flag interrupt. 0b - Disables the round-robin flag interrupt. 1b - Enables the round-robin flag interrupt when the comparison result changes for a given channel.
1 CFF_IE	Comparator Flag Falling Interrupt Enable Enables or disables the comparator flag falling interrupt. 0b - Disables the comparator flag falling interrupt. 1b - Enables the comparator flag falling interrupt when CFF is set.
0 CFR_IE	Comparator Flag Rising Interrupt Enable Enables or disables the comparator flag rising interrupt. 0b - Disables the comparator flag rising interrupt. 1b - Enables the comparator flag rising interrupt when CFR is set.

61.7.9 Comparator Status (CSR)

Offset

Register	Offset
CSR	20h

Function

Indicates comparator status, including COUT, CFF, CFR, and RRF.

NOTE

LPCMP may output a glitch and affect the value of CSR[CFF] and CSR[CFR] at the moment of enabling CMP. In order to ensure correctness, it is recommended to write one to clear (W1C) CSR[CFF] and CSR[CFR] before further configuring CMP.

Chapter 62
Logic Control Unit (LCU)

62.1 Chip-specific LCU information

62.1.1 LCU instances

This chip has two identical LCU instances, LCU_0 and LCU_1.

62.2 Overview

LCU selects multiple inputs from timers, Pulse Width Modulation (PWM) signals, and Input/Output (I/O) pads, and combines them using a programmable logic function to create output waveforms.

62.2.1 Block diagram

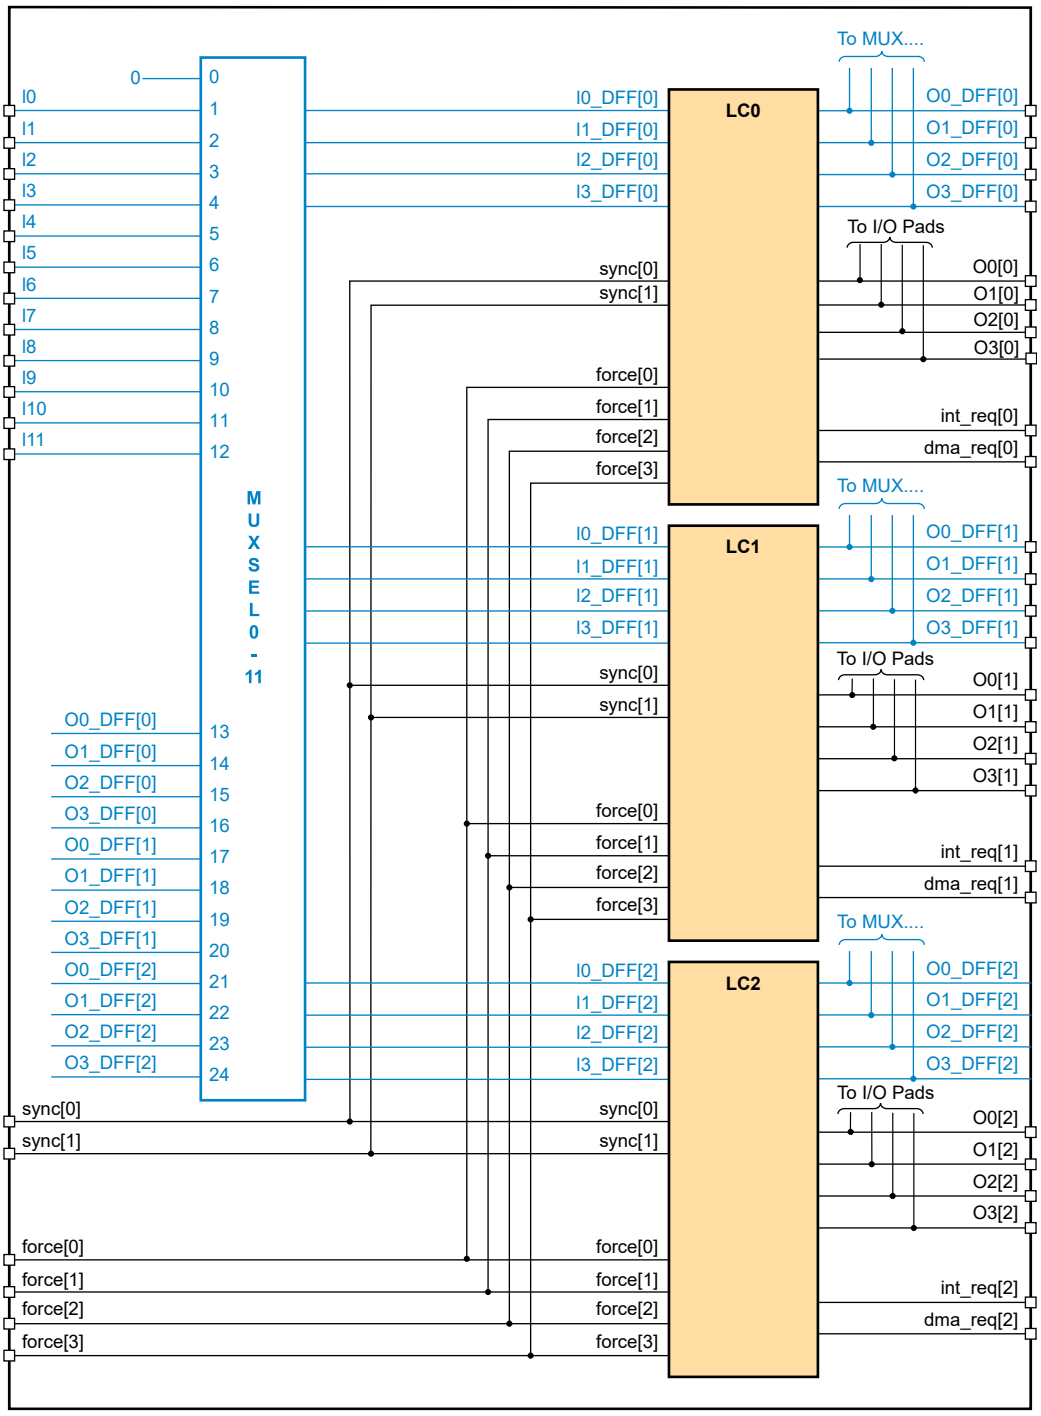

Figure 279. Block diagram

NOTE

3 LCs are shown in this block diagram.

62.2.2 Features

- 3 LCs with programmable logic function for generating output results
- 12 inputs to and 12 outputs from LCs
- Muxing to map any input to any LC
- Independent filters for the rising and falling output states of each LC
- Software override logic for inputs using multiple modes
- 3 force inputs with programmable edge filtering to force output states using multiple modes
- 2 sync inputs to control transition timing
- Lock bit to block writes to configuration registers
- Interrupt request generation based on output change or force event
- DMA transfer request generation based on output change or force event

62.3 Functional description

62.3.1 LC operation

62.3.1.1 Overview

An LC performs logic operations based on the LUT principle, as described in Logic operations.

Each LC supports the following features:

- Independent filter thresholds for the rising and falling output states support different transition delays.
- Bypass of the output state filter by setting the filter threshold to zero. Bypassing the filter causes the asynchronous signal to propagate to the output of the LC.
- Force logic that instantly switches an LC output to the inactive state upon external fault signal assertion. The return from the inactive state to the output state is either:
  - Instantaneous: when LCU deasserts the force signal.
  - Instantaneous synchronized: when LCU deasserts the force signal and then the sync input asserts.
  - Manual: when you write 1 to the force status bit and then the LCU deasserts the force input.
  - Manual synchronized: when you write 1 to the force status bit and LCU deasserts the force input, and then the sync input asserts.
- Input software override logic to override external inputs by writing to the following registers:
  - LC*n* Sync Control (LC*n*_SCTRL[SW_MODE])
  - Software Override Value (SWVALUE[SWVALUE])
  - Software Override Enable (SWEN[SWEN])
- Generation of interrupt requests or DMA transfer requests.

62.3.1.2 LC diagram

This figure illustrates an example LC implementation with:

- One LC
- Four force inputs
- Two sync inputs

For the number of each resource in this chip, see Features.

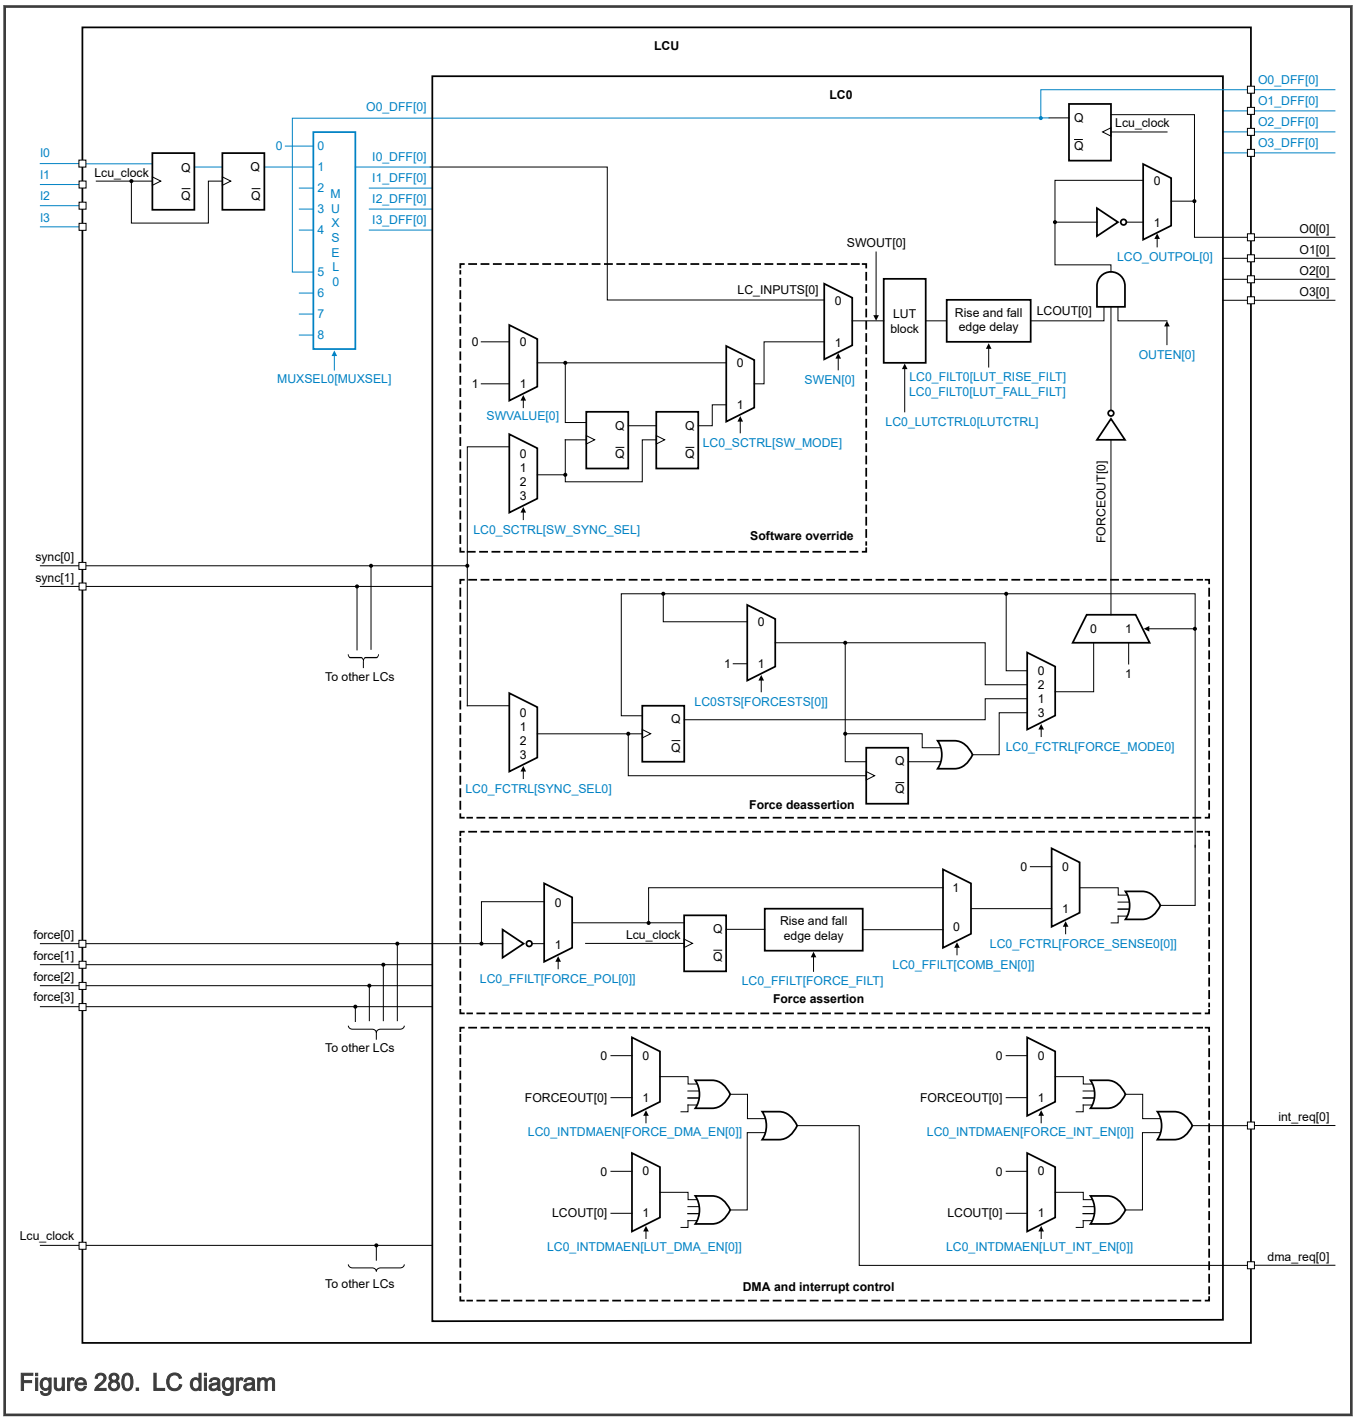

Figure 280. LC diagram

62.3.1.3 Logic operations

An LC reads its set of inputs (inputs 3, 2, 1, and 0) as a four-bit binary value, with Input 3 as the most-significant bit and Input 0 as the least-significant bit. For example, if:

Input 0 = 0

Input 1 = 1

Input 2 = 0

Input 3 = 1

then the combined input value is 1010b (10 decimal).

Each possible four-bit input value corresponds to a bit position in the LUT Control (LCn_LUTCTRLm[LUTCTRL]), as illustrated in LC LUT. For a given LC output, if the combined LC input value corresponds to a bit position in that output's LUTCTRL value that equals 1, then the LC asserts that output.

For example, if you write 35h to LUTCTRL (shown in the Example column of the LC LUT), then the combined input values 0 (0000b), 2 (0010b), 4 (0100b), and 5 (0101b) cause assertion of the output. All other input values cause deassertion of the output.

LCU processes each look-up table asynchronously.

62.3.1.4 LC LUT

The LUT maps the combined LC input value to a bit position in LC*n*_LUTCTRL*m*.

Table 355. LC LUT

Input 3	Input 2	Input 1	Input 0	LUTCTRL bit position	Example LUTCTRL value: 35h
0	0	0	0	0	1
0	0	0	1	1	0
0	0	1	0	2	1
0	0	1	1	3	0
0	1	0	0	4	1
0	1	0	1	5	1
0	1	1	0	6	0
0	1	1	1	7	0
1	0	0	0	8	0
1	0	0	1	9	0
1	0	1	0	10	0
1	0	1	1	11	0
1	1	0	0	12	0
1	1	0	1	13	0
1	1	1	0	14	0
1	1	1	1	15	0

62.3.1.5 LC output filters

Each LC supports two optional digital filters, a Rise Filter (LC*n*_FLIT*m*[LUT_RISE_FILT]) and a Fall Filter (LC*n*_FLIT*m*[LUT_FALL_FILT]), to post-process the LUT output and delay the output signal change.

Each filter starts accumulating clock cycles on the occurrence of the associated LUT event. The Rise Filter counts from an output assertion, and the Fall Filter counts from an output deassertion. When the number of clock cycles reaches the filter threshold (matches the specified filter value), the output flips to the new state. For example, if you specify a Rise Filter value of 100h, and the LUT event triggers an output assertion, the output signal does not assert until the 256th clock cycle after the event.

A filter value of 0 bypasses the filter.

NOTE

LCU usecase (intercell/feedback loop path along with TRGMUX Path) does not work with default RISE/FALL filter time. You must configure RISE/FALL Filter delay at least for 1 cycle to avoid such glitches/failures.

62.3.2 Behavior in different chip modes of operation

Table 356. Modes of operation

Operation mode	Status of outputs
Normal	• Controlled by LC*n*_LUTCTRL*m* and MUXSEL*n* • Toggled based on the states of the selected inputs
Debug	Inactive or normal operation controlled by Debug Mode Enable (DBGEN)

62.3.3 Clocking

This module has no clocking considerations.

62.3.4 Interrupts

Each LC has a single interrupt request output int_req[n]. Interrupt request enables bits for all the 4 outputs in each LC defined in LC*n*_INTDMAEN with LC*n*_INTDMAEN[FORCE_INT_EN] for interrupt request generation when a force event occurs and LC*n*_INTDMAEN[LUT_INT_EN] for interrupt request generation when a LUT event occurs.

When user enables interrupt for a force event on an output and the force event occurs on that output, LCU generates an interrupt request if LC*n*_STS[FORCESTS] and LC*n*_INTDMAEN[FORCE_INT_EN] for that output is 1. Similarly when user enables interrupt for a LUT event on an output and a LUT event occurs on that output, LCU generates an interrupt request if LC*n*_STS[LUT_STS] and LC*n*_INTDMAEN[LUT_INT_EN] for that output is 1.

62.3.5 DMA

Each LC has a single DMA request output dma_req[n]. DMA request enables bits for all the 4 outputs in each LC defined in LC*n*_INTDMAEN with LC*n*_INTDMAEN[FORCE_DMA_EN] for DMA request generation when a force event occurs and LC*n*_INTDMAEN[LUT_DMA_EN] for DMA request generation when a LUT event occurs.

When user enables DMA for a force event on an output and the force event occurs on that output, LCU generates a DMA request if LC*n*_STS[FORCESTS] and LC*n*_INTDMAEN[FORCE_DMA_EN] for that output is 1. Similarly when user enables DMA for a LUT event on an output and a LUT event occurs on that output, LCU generates a DMA request if LC*n*_STS[LUT_STS] and LC*n*_INTDMAEN[LUT_DMA_EN] for that output is 1.

62.4 External signals

This module has no external signals.

62.5 Initialization

This module does not require initialization.

62.6 Application information

62.6.1 Use-case examples

62.6.1.1 Two-channel multiplexer

62.6.1.1.1 Overview

A multiplexer (or mux) takes multiple inputs and, based on some control mechanism, passes only one of those inputs to the output. You can implement a two-channel multiplexer controlled by an external signal or a software override using three inputs and one output of a single LC, as illustrated in Logic diagram and Implementation.

This example implementation controls the multiplexer with the SEL input signal and a software override. The software override controls the multiplexer output regardless of the SEL signal state. To use software override, you must enable it for the corresponding output (SWEN[SWEN]). You assert software override by writing 1 to the corresponding bit of the Software Override Value (SWVALUE[SWVALUE]).

62.6.1.1.7 Waveforms

In this figure, the SWEN and SWVALUE signals represent the states of the software override control registers. Writes to SWEN and SWVALUE have immediate impact on LC outputs, whereas LC inputs require input synchronization to prevent metastability.

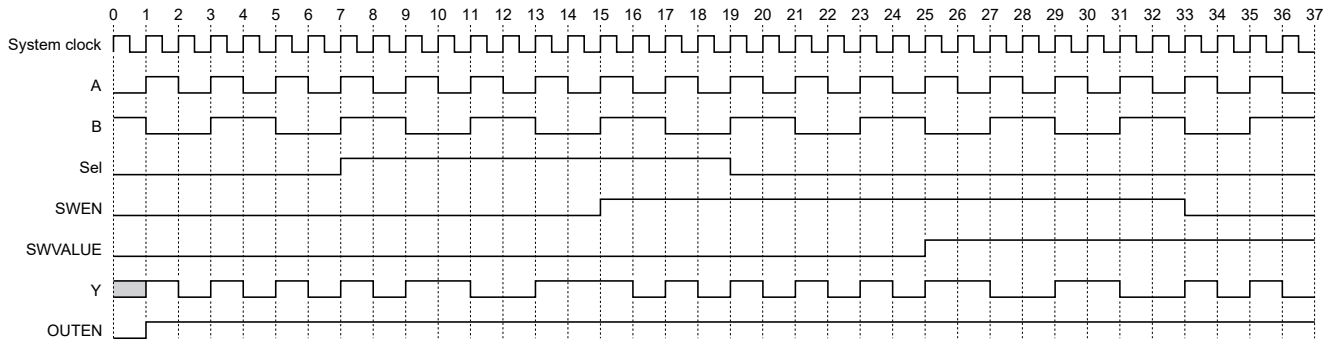

Figure 283. Waveforms

62.6.1.2 Binary to Gray code converter

62.6.1.2.1 Overview

Gray code, also known as reflected binary code (RBC), is a non-weighted, minimum change code. In this code, any two adjacent code numbers differ by only one bit. This code solves the problem of physical switch transitions by changing only one switch at a time, so there is never any ambiguity of position.

You can implement binary to Gray code conversion using a single LC, as illustrated in Logic diagram and Implementation.

In this example, the LC also generates a DMA request on each rising edge of output 3, which is bit 0 of the Gray code (G0).

62.6.1.2.2 Conversion table

Table 360. Conversion table

62.6.1.3 Manchester encoder and decoder

62.6.1.3.1 Overview

Manchester encoding (also known as phase encoding) is a data-modulation technique for binary data transfer based one of these signals:

- Analog
- RF
- Optical
- High-speed-digital
- Long-distance-digital

The fundamental idea behind Manchester encoding is to use voltage transitions, instead of voltage levels, to represent 1s and 0s. It performs an exclusive OR of data and clock signals to encode and decode data. A high-to-low transition on the falling clock edge indicates 0. A low-to-high transition on the rising clock edge indicates 1.

62.6.1.3.8 Waveforms for encoder

This figure includes the Manchester-encoded waveform (labeled PE) of the input waveform (labeled "Data in"). The PE waveform is delayed by two clock cycles because of two-stage input synchronization.

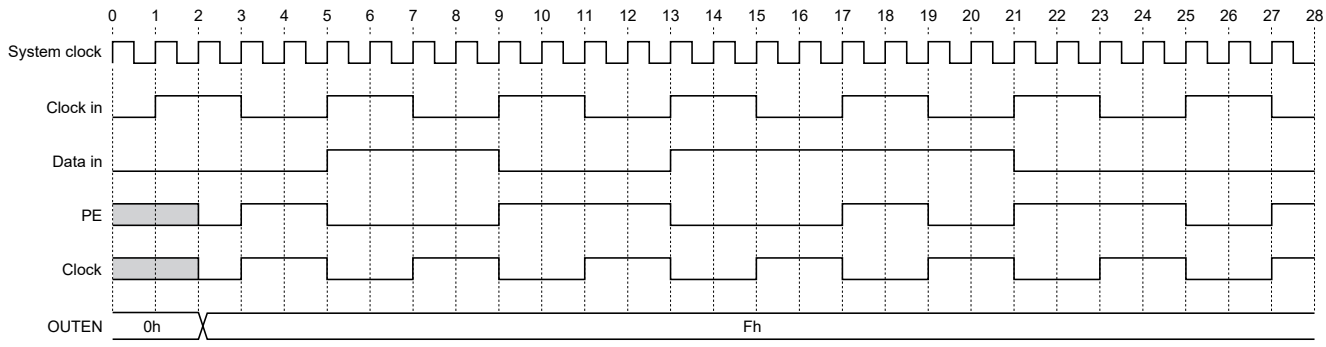

Figure 289. Waveforms for encoder

62.6.1.3.9 Waveforms for decoder

The output waveform (labeled "Data out") is delayed by four clock cycles from the input waveform (labeled "Data in") because of two-stage input synchronization. In this example, the Manchester encoder also propagates the Clock waveform that the decoder uses to reconstruct the "Data in" waveform from the Manchester-decoded waveform (labeled PE).

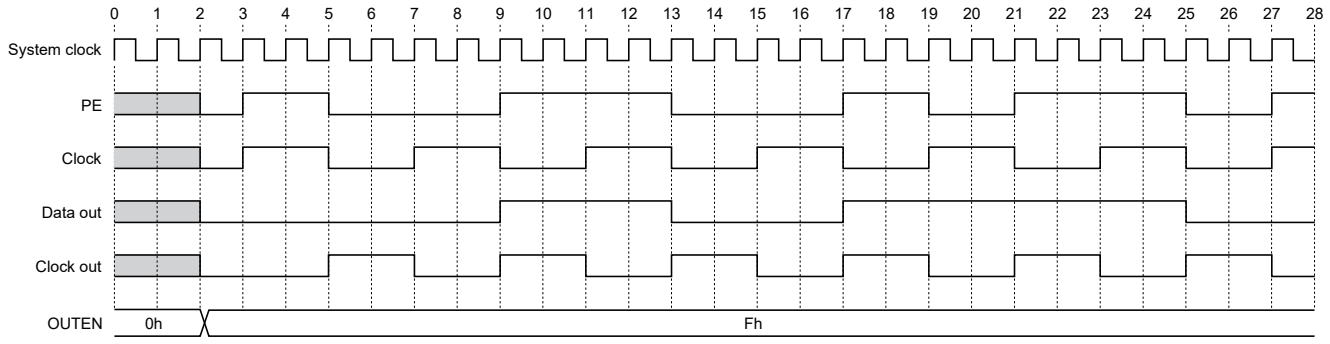

Figure 290. Waveforms for decoder

62.6.1.4 Adjustable PWM/FM generator

62.6.1.4.1 Overview

In many cases, it is useful to route an LC output back to one of its inputs, as illustrated in Implementation. In addition, you can delay outputs with a digital filter with different time constants for delaying rising and falling edges. Combining these capabilities, you can use an LC to generate output waveforms with adjustable pulse width and frequency.

In addition to waveform generation, the software-override feature forces the generator output low or high by software. You control the override via Software Override Enable (SWEN) and Software Override Value (SWVALUE).

62.6.1.4.2 Implementation

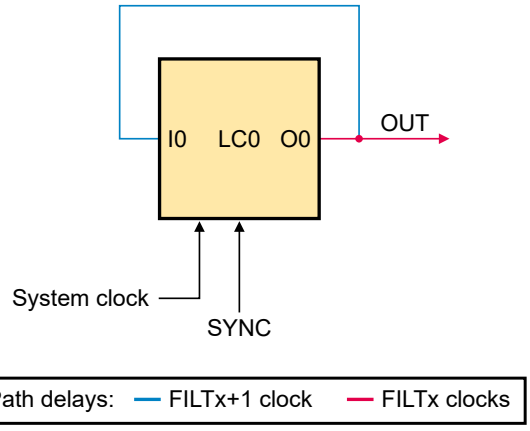

Figure 291. Implementation

62.6.1.4.3 Connections and controls

Table 368. Connections and controls

Name	Description
I0	Delayed output routed back to LC input
O0 and OUT	Delayed output
System clock	Clock frequency supplied to LC
SYNC	Software override synchronization signal

62.6.1.4.4 Truth table

This example generates an adjustable PWM/FM waveform according to the following table. In the table:

- OUT is the LC output signal that is also routed to the LC input using an internal multiplexer.
- TdH is the digital filter value to delay the rising edge of the output signal.
- TdL is the digital filter value to delay the falling edge of the output signal.

Table 369. Truth table

I0	OUT
0	1 delayed by TdH (see Output edge delays)
1	0 delayed by TdL (see Output edge delays)

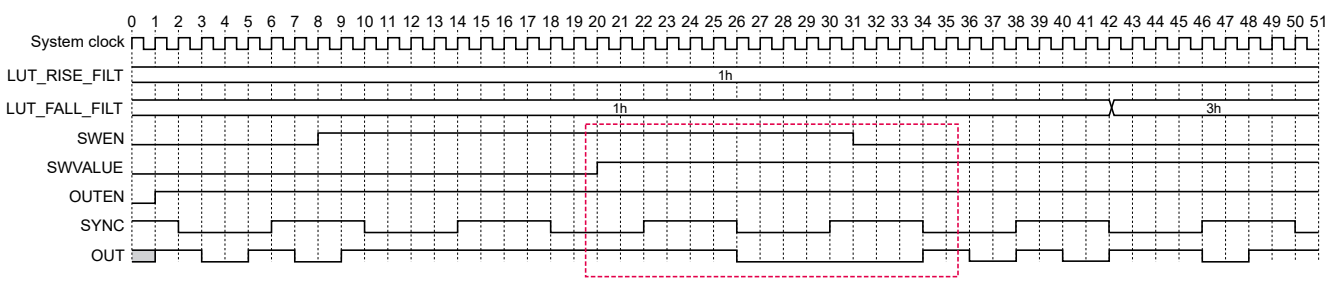

Figure 294. Waveforms for synced software override

62.6.1.5 SR latch

62.6.1.5.1 Overview

An SR latch is the simplest bistable device and a fundamental component of data storage.

This example implementation uses one LC that includes an internal feedback path configured by the internal multiplexer, as illustrated in Implementation. Output Q responds to inputs S (set) and R (reset). It changes with a delay of two clock cycles—the time required for the S and R signal inputs to pass through the internal two-stage synchronizers. This example implementation bypasses the Q digital filter; therefore, the loop of Q back to the input experiences a delay of one clock cycle." See Waveforms.

62.6.1.6 D flip-flop

62.6.1.6.1 Overview

A D flip-flop stores and outputs whatever logic level is applied to its data terminal at the time its clock input goes high.

You can implement a D flip-flop element using an LC as illustrated in Implementation. On a clock rising edge, the LC either asserts or deasserts the Q output based on the D input.

The Q output and CLKO digital filters are bypassed. Therefore, the states of these variables are fed to inputs with a delay of one clock cycle. See Waveforms.

62.6.1.7 JK flip-flop

62.6.1.7.1 Overview

A JK flip-flop is a gated SR latch (see SR latch) with an added clock input circuit that prevents the illegal or invalid output condition that can occur when both SR-latch inputs (S and R) are asserted.

Truth table for JK flip-flop presents the four possible input combinations for a JK flip-flop. All output changes occur at the clock rising edge.

You can create a JK flip-flop using two LCs, as illustrated in Implementation. The first LC detects rising edges of the CLK clock input (see Truth table for LC0). The second LC processes J and K inputs at every rising clock edge (see Truth table for LC1).

Output Q and CLKO digital filters are bypassed. Therefore, the states of these variables are fed to inputs with a delay of one clock cycle (see Waveforms).

62.6.1.7.8 Waveforms

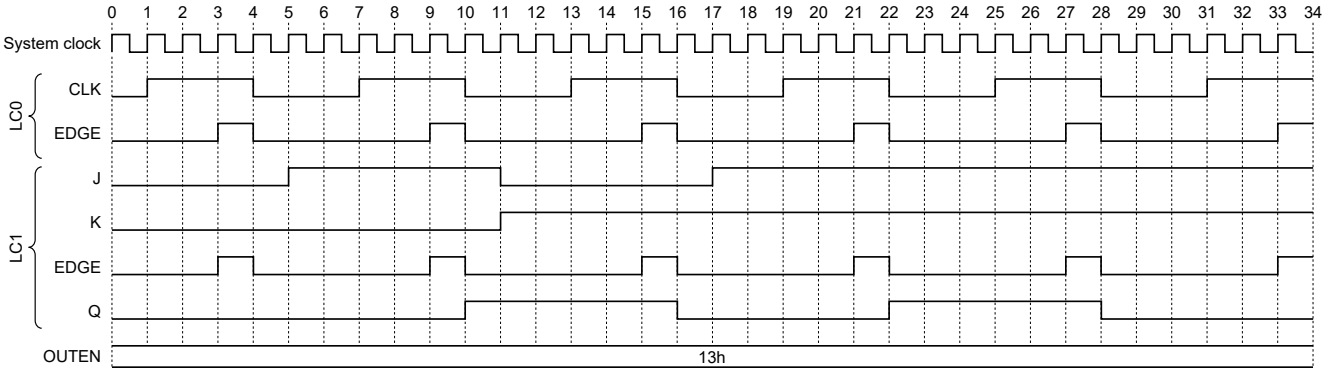

Figure 300. Waveforms

62.6.1.8 Incremental encoder

62.6.1.8.1 Overview

An incremental encoder provides A and B pulse outputs in the form of 90-degree shifted waveforms (see Outputs). The decoding circuit processes these waveforms to detect the rotor position and the direction of rotation.

This example implementation requires two LCs (see Implementation):

- LC0 provides pulse streams on CW or CCW output at every A and B signal edge. If the encoder rotation is CW (A signal leading), then pulses appear at the CW output. If the encoder rotation is CCW (B signal leading), then pulses appear at the CCW output. Two pulse counters accumulate these pulse streams to provide the actual absolute encoder position in the respective direction of rotation.
- LC1 then uses the LC0 outputs to detect the direction of the rotation.

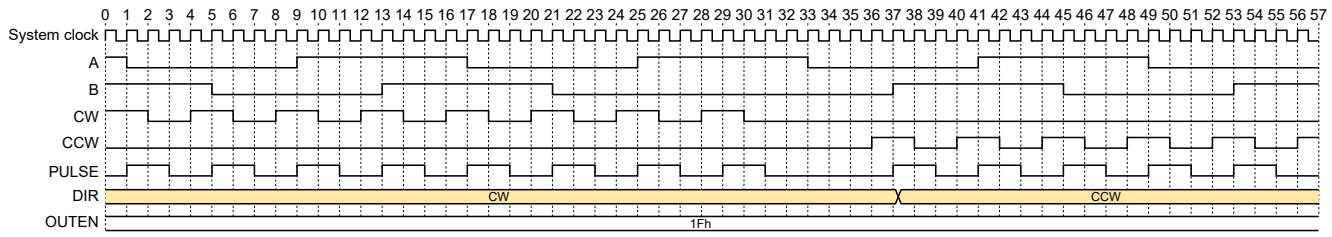

Figure 303. Waveforms

62.6.1.9 AC motor PWM controller

62.6.1.9.1 Overview

Driving a three-phase AC motor requires dedicated PWMs to perform:

- Complementary signal generation
- Dead time insertion
- Fault-state assertion
- Manual or automatic fault recovery

LCU enhances basic timer functionality with the necessary complementary features available only on dedicated motor control PWMs.

Implementation for AC motor controller shows all input and output signals of LCU in a typical three-phase motor control application.

TdH is the time delay preceding each rising edge of the complementary PWM output signals. See Truth table for details.

Fault signals are routed from analog comparators or external protection circuits to protect power switches against damage caused by overcurrent. Any active fault must immediately change all PWM outputs to the inactive state. Force logic causes PWM outputs to transition to the inactive state upon an external fault event. See Truth table for details.

The dead time is one clock cycle. On a fault event, both PWM outputs transition to the inactive state (logic 0). When the fault event deasserts, both PWM signals start operating according to FORCE_MODE = 00 (cleared on force deassertion). See Waveforms for force cleared on force deassertion for details.

62.6.1.9.7 Waveforms for force cleared on force deassertion

This example shows two behaviors, depending on the Force Clearing mode (LC0_FCTRL[FORCE_MODE0]).

00b - Both PWM signals start normal operation when the fault event deasserts. See Waveforms for force cleared on force deassertion for details.

01b - Both PWM signals start normal operation on rising sync after the fault event deasserts. See Waveforms for force cleared on rising sync after force deassertion for details.

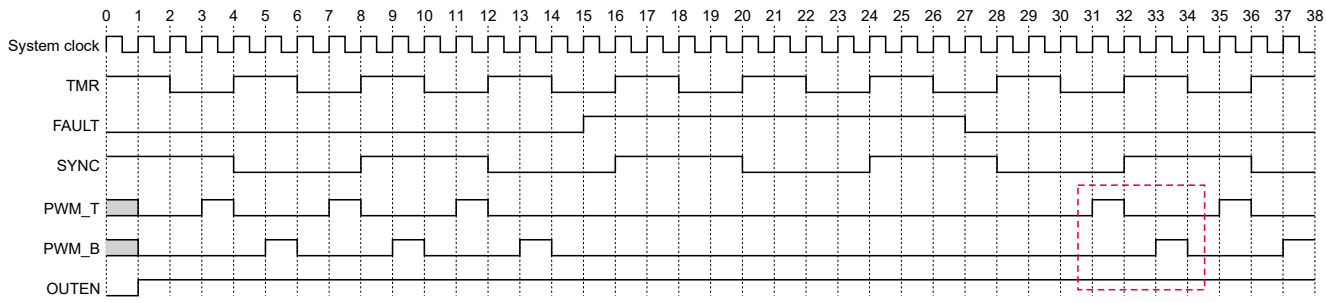

Figure 306. Waveforms for force cleared on force deassertion

62.6.1.9.8 Waveforms for force cleared on rising sync after force deassertion

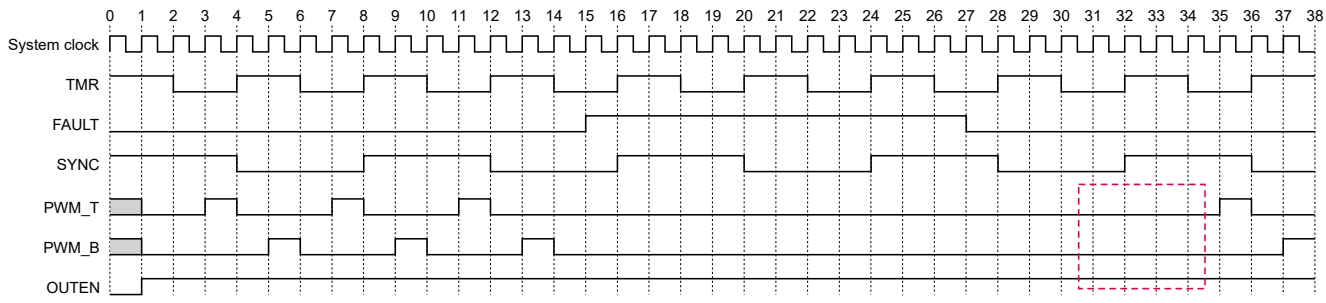

Figure 307. Waveforms for force cleared on rising sync after force deassertion

62.6.1.10 AC motor double-switching controller

62.6.1.10.1 Overview

The simplest method of obtaining motor winding currents is to measure the current in each phase by placing a shunt resistor in two or three inverter legs (phases).

This example implementation of an AC motor drive for low-cost and high-volume applications uses a single shunt on the DC bus return path, as illustrated in AC motor power stage schematic. LCU supports double-switching by XORing two timer channel outputs. The implementation uses two LCs arranged to perform double switching, dead time generation, and the processing of three external fault signals.

62.6.1.10.2 Double-switching

The double-switching technique requires:

- Six synchronized timer pulses
- Three fault signals
- Six PWM outputs for controlling top and bottom power switches
- A sync signal for automatic fault recovery

Waveforms for double-switching technique example applies the PWM switching cycle to an AC motor to reconstruct currents in three phases using a single DC bus shunt resistor (RSH). It applies the non-zero switching vectors 100, 110, and 101 to the power switches, which sample currents IA[0], -IC[0], -IC[1], and IA[1]. Because the durations (T1) of active vectors 110 and 101 are the same, it also applies the zero switching vector (000) with durations T2 and T3 in the middle of the switching cycle to allow phase current reconstruction. This technique can only be used by PWM modules targeted at motor control and power conversion applications.

62.6.1.10.3 Fault inputs and deadtime insertion

Fault signals are routed from analog comparators or external protection circuits to protect power switches against damage caused by overcurrent. You must program the Combinational Force Path (LCn_FFILT[COMB_EN]) to enable an active fault input to immediately force all PWM outputs to the inactive state.

62.6.1.10.4 Deadtime insertion

In Waveforms for generation of PWM complementary signals using an LC, the PWMA_T output is generated by XORing timer outputs TMR0 and TMR1. The PWMA_B output is complementary to PWMA_T. Digital filters insert a dead time of one system clock cycle to delay the rising edges of both PWM signals.

62.6.1.10.5 Fault events

Waveforms for force cleared on force deassertion shows the reaction to the fault event. On a fault event, both the PWM outputs transition to the inactive state (logic 0). When fault event deasserts, both the PWM signals start operating according to FORCE_MODE = 00 (cleared on force deassertion).

Alternatively, after the fault event deasserts, fault clearing can be performed according to FORCE_MODE = 01 (cleared on rising sync force deassertion). See Waveforms for force cleared on rising sync after force deassertion for details.

62.6.1.11 Brushless DC (BLDC) motor PWM controller

62.6.1.11.1 Overview

You can use LCU to replace the mechanical commutator in the BLDC motor control application with Hall-sensor position measurement.

In this example implementation, LC0 receives the direction (DIR) and Hall A, Hall B, and Hall C sensor output states, and from those inputs generates the switching states S1, S2, and S3. LC1 and LC2 convert the switching states to PWM or on-off signals for controlling power switches, as illustrated in Waveforms for BLDC motor control technique.

BLDC motor power stage schematic and BLDC motor electrical arrangement illustrate a three-phase BLDC motor power stage with switching pulses and phase currents controlling motor rotation in the CCW direction. The state of the Hall sensors is 010. As the rotor shaft rotates, Hall sensors track the motor position. You accelerate or decelerate the motor by controlling the width of the PWM signal. You can include one or more faults (force inputs) to force power switches instantaneously into the inactive state if there is an overcurrent.

62.6.1.11.2 Implementation

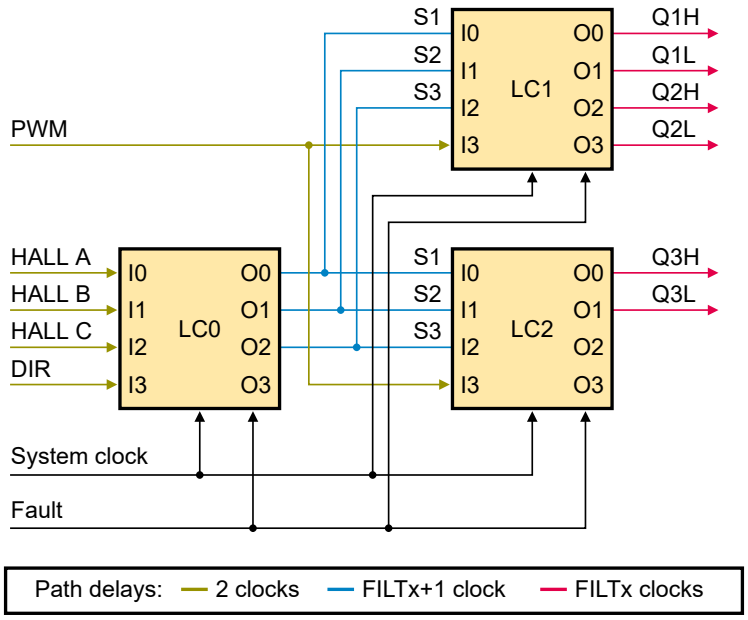

Figure 315. Implementation

62.6.1.11.3 BLDC motor power stage schematic

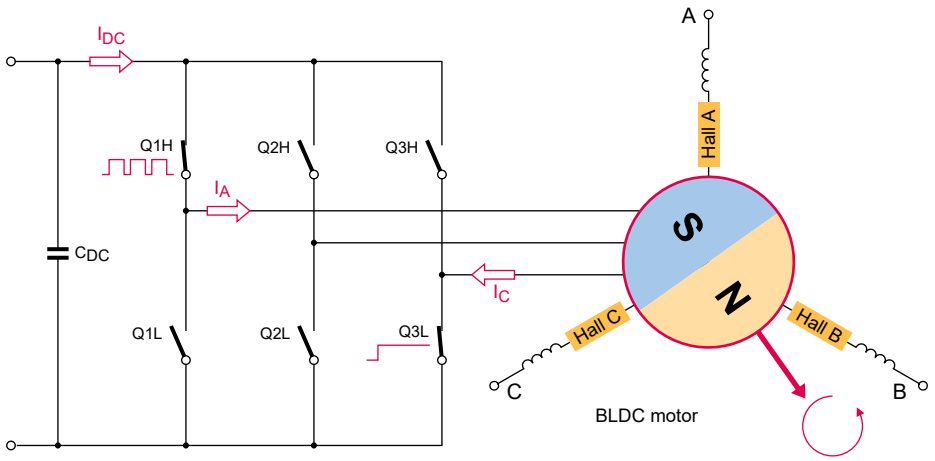

Figure 316. BLDC motor power stage schematic

62.6.1.11.4 BLDC motor electrical arrangement

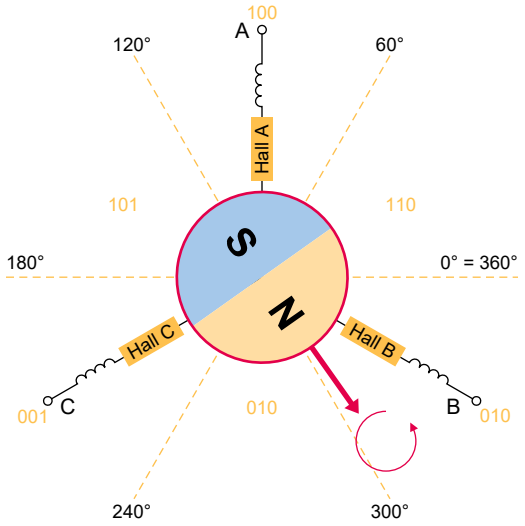

Figure 317. BLDC motor electrical arrangement

62.6.1.11.5 Waveforms for BLDC motor control technique

This figure illustrates the basic waveforms for controlling a BLDC motor with stator windings and Hall sensors arranged according to BLDC motor electrical arrangement. Configure the external hardware (motor or sensor) so that it can produce these waveforms; then you can configure LCU.

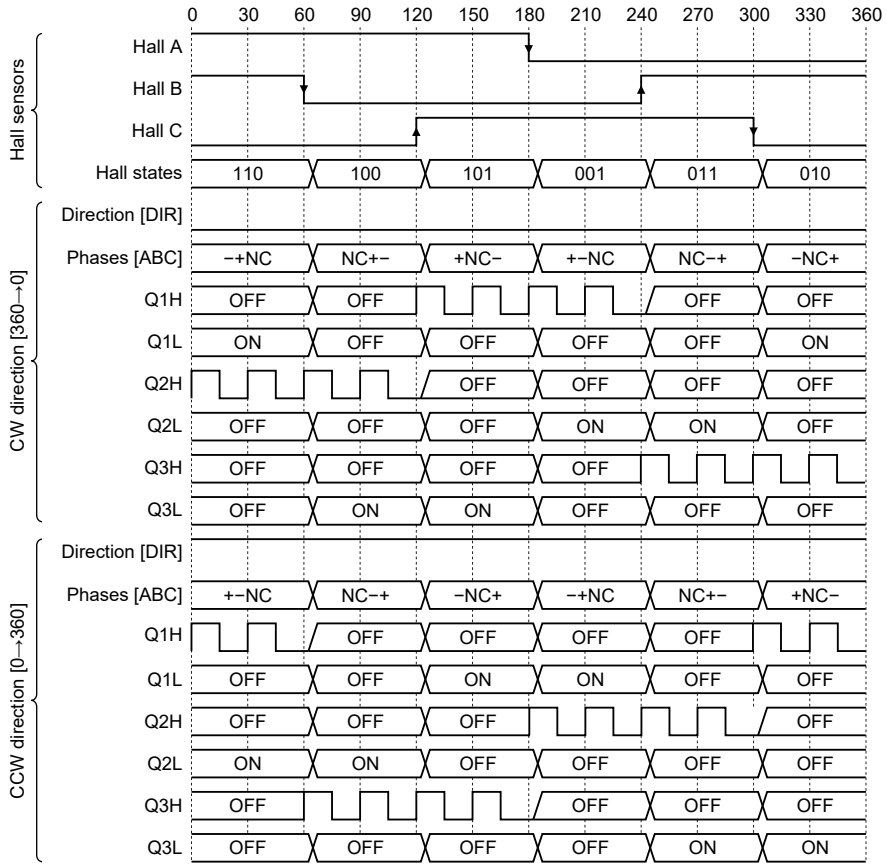

Figure 318. Waveforms for BLDC motor control technique

62.6.1.11.6 Connections and controls

Table 392. Connections and controls

Input-output group	Name	Description
LC0 inputs	HALL A	Hall sensor A output state
	HALL B	Hall sensor B output state
	HALL C	Hall sensor C output state
	DIR	Direction of shaft rotation, as illustrated in Waveforms for reversing BLDC motor.
LC1 and LC2 inputs	S1	Switching state 1 (output 0 from LC0)
	S2	Switching state 2 (output 1 from LC0)
	S2	Switching state 3 (output 2 from LC0)
	PWM	Output from PWM
LC0, LC1, and LC2 inputs	Clock	LCU clock input
	Fault	Optional fault input

Table continues on the next page...

Table 392. Connections and controls (continued)

Input-output group	Name	Description
LC1 outputs	Q1H	Motor control switch outputs, as illustrated in BLDC motor electrical arrangement
	Q1L	
	Q2H	
	Q2L	
LC2 outputs	Q3H	
	Q3L	

62.6.1.11.7 Truth table for generating switching states

This table includes all Hall sensor states, even those that never occur because of sensor displacement by 120°.

Table 393. Truth table for generating switching states

Inputs				Outputs			Comments

62.6.1.11.13 Waveforms for reversing BLDC motor

This figure illustrates the waveforms for controlling a reversing BLDC motor. The DIR input indicates the direction of rotation:

- Logic 0 for CW rotation
- Logic 1 for CCW rotation

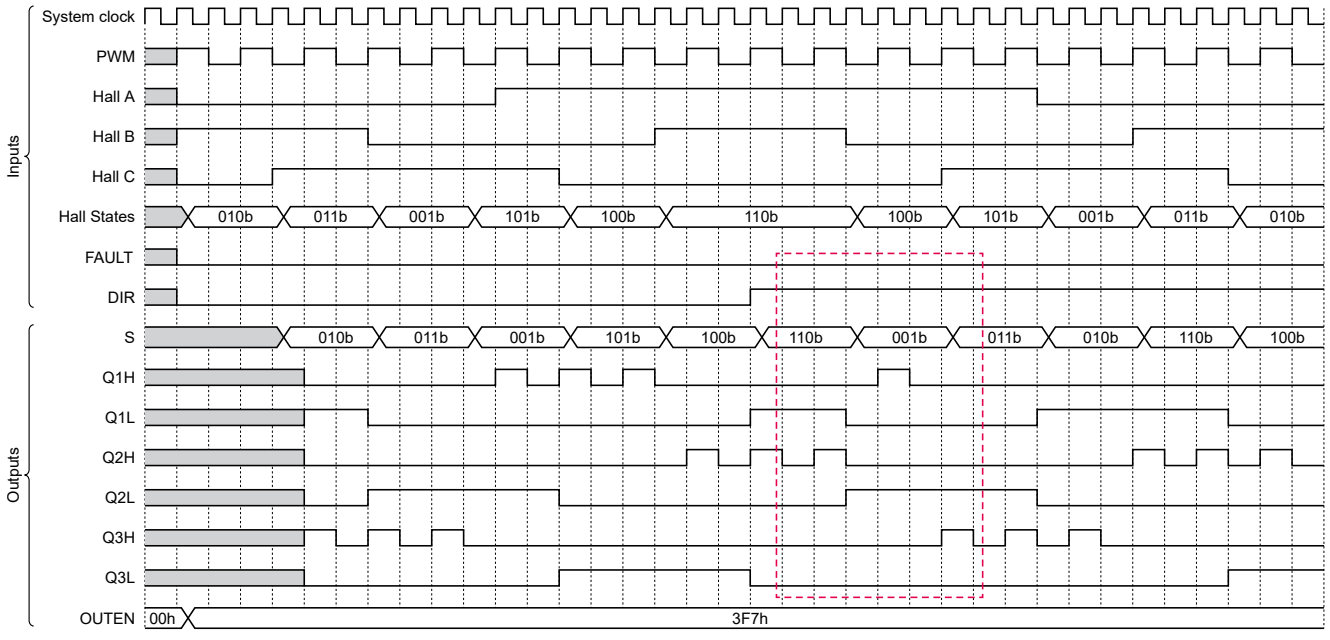

Figure 319. Waveforms for reversing BLDC motor

62.6.1.11.14 Waveforms for reversing BLDC motor with fault assertion

This figure illustrates the waveforms for the reaction to an external fault in addition to reversing the BLDC motor. On the occurrence of an external fault event, the power switches transition to the inactive state (logic 0). Two clock cycles after external fault deassertion, the power switches start operating normally.

Switching state outputs S1, S2, and S3, generated by LC0, receive an additional delay of one clock cycle on their way to the inputs of other LCs (digital filters bypassed).

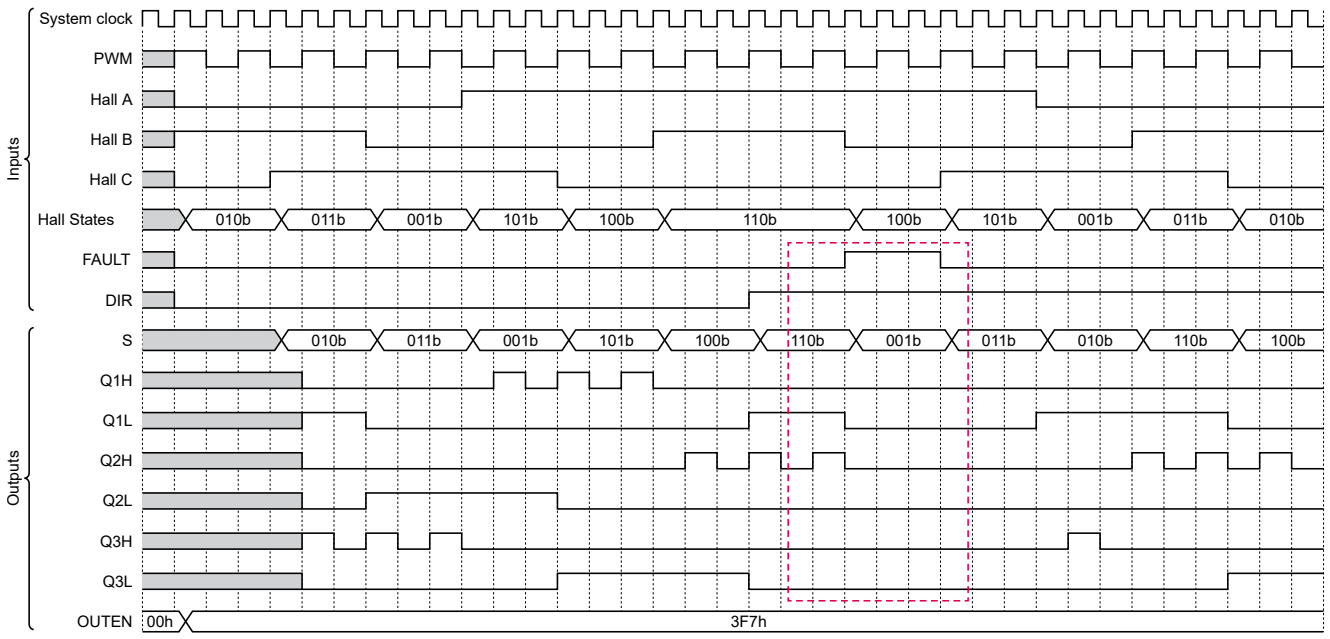

Figure 320. Waveforms for reversing BLDC motor with fault assertion

62.7 Mapping of 12-bit input, output, and state fields

This table maps inputs, outputs, or states to the bit positions in the following 12-bit fields:

- SWEN[SWEN]
- SWVALUE[SWVALUE]
- OUTEN[OUTEN]
- LCIN[LC_INPUTS]
- SWOUT[SWOUT]
- LCOUT[LCOUT]
- FORCEOUT[FORCEOUT]
- FORCESTS[FORCESTS]
- DBGEN[DBGEN]

62.8.2 LC n Output m LUT Control (LC0_LUTCTRL0 - LC2_LUTCTRL3)

Offset

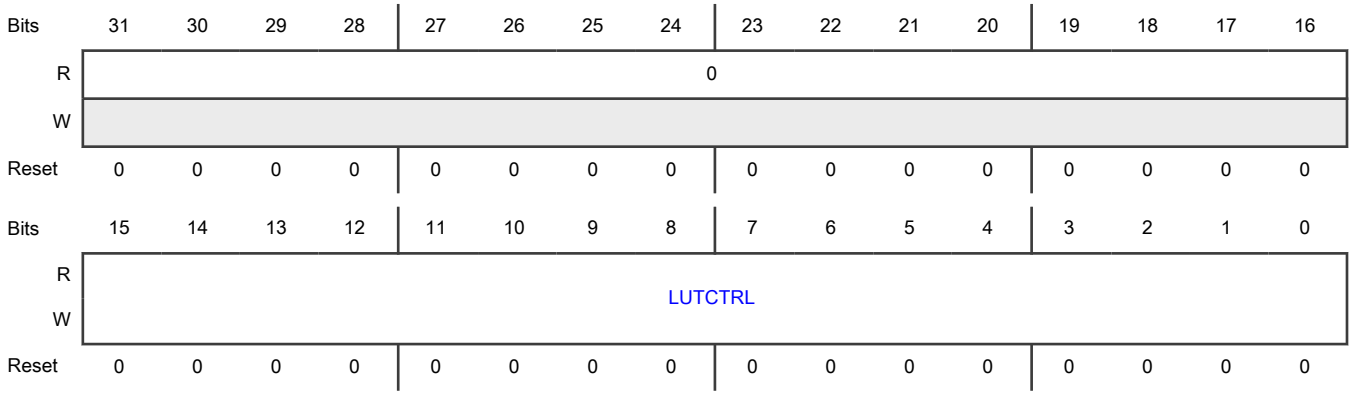
For n = 0 to 2; m = 0 to 3:

Register	Offset
LCn_LUTCTRLm	0h + (n × 40h) + (m × 4h)

Function

See LUTCTRL.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 LUTCTRL	LUT Control Specifies the LUT positions, based on the combined LC input value, that result in assertion of this output. For more information, see Logic operations.

62.8.3 LC n Output m Filter (LC0_FILT0 - LC2_FILT3)

Offset

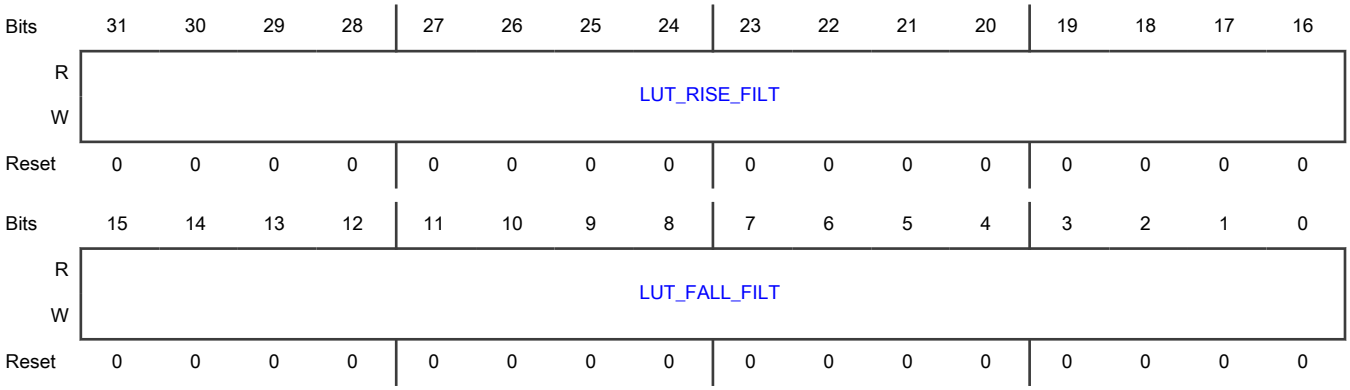
For n = 0 to 2; m = 0 to 3:

Register	Offset
LCn_FILTm	10h + (n × 40h) + (m × 4h)

Function

Specifies the rising- and falling-edge thresholds for the LC output filters.

Diagram



Fields

Field	Function
31-16 LUT_RISE_FILT	Rise Filter Specifies the number of consecutive clock cycles the filter output must be logic 1 before the output signal goes high. 0000_0000_0000_0000b - Bypass filter All other values - Filter threshold

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-0 LUT_FALL_FILT	Fall Filter Specifies the number of consecutive clock cycles the filter output must be logic 0 before the output signal goes low. 0000_0000_0000_0000b - Bypass filter All other values - Filter threshold

62.8.4 LC n Interrupt and DMA Enable (LC0_INTDMAEN - LC2_INTDMAEN)

Offset

Register	Offset
LC0_INTDMAEN	20h
LC1_INTDMAEN	60h
LC2_INTDMAEN	A0h

Function
Enables interrupt and DMA requests for LUT and force events.

Fields

Field	Function
31-12 —	Reserved
11-8 FORCESTS	Force Event Indicates that a force event has occurred on the associated output. For each bit: 0b - No event 1b - Event occurred Mapping of bits:

Output	Register bit
0	8
1	9
2	10
3	11

When you enable DMA for a force output (LC*n*_INTDMAEN[FORCE_DMA_EN]) and a force event occurs on that output, LCU generates a DMA request. The resulting DMA done signal causes LCU to change the bit to 0, or you can write 1 to the bit.

You can also change these bits to 0 by writing to the corresponding Force Status bits (FORCESTS[FORCESTS]).

The timing of status clearing depends on the selected Force Mode (LC*n*_FCTRL[FORCE_MODEm]).

7-4 —	Reserved
3-0	LUT Event

Table continued from the previous page...

<table>

62.8.7 LC n Force Filter (LC0_FFILT - LC2_FFILT)

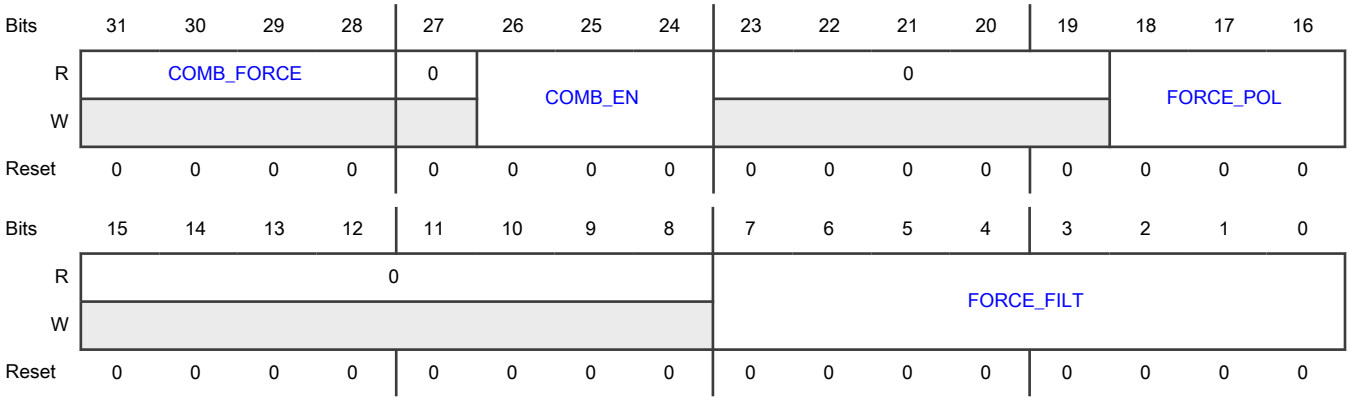
Offset

Register	Offset
LC0_FFILT	2Ch
LC1_FFILT	6Ch
LC2_FFILT	ACh

Function

Controls the force filter for this LC.

Diagram



Fields

Field	Function
31-28 COMB_FORCE	Combined Sensed Force Input Indicates the combined value of force inputs to each output. For each bit: 0b - Logic low 1b - Logic high Mapping of bits:

Output	Bit
0	28
1	29
2	30
3	31

Field	Function
27 —	Reserved
26-24 COMB_EN	Combinational Force Path (CFP) Enable Enables an active force input to combinationally affect the LC outputs. When CFP is not enabled, force inputs must be synchronized and then optionally filtered. When you enable CFP (write 1 to one of these bits), the corresponding force input bypasses synchronization and filtering and immediately affects the LC output. The Force Filter (FORCE_FILT) is still in effect. Force inputs that do not meet the pulse width requirements for synchronization and filtering are not registered in Force Status (FORCESTS) and you do not need to write 1 to change the bit to 0.

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>CFP provides a safety factor when the LC outputs drive a motor and immediate response is required. In some topologies, an oscillation can result if the assertion of the force input causes the LC output to turn off. This situation in turn leads to deassertion of the force input and the output turning back on. In general, you must disable CFP unless the LCU outputs drive a motor or similar safety-critical application, which requires an immediate response without synchronization delays.</td></tr>
<tr><td>23-19
—</td><td>Reserved</td></tr>
<tr><td>18-16
FORCE_POL</td><td>Force Input Polarity
Specifies the polarity of the force inputs to this LC.
For each bit:
0b - Not inverted
1b - Inverted
Mapping of bits:
<table><tr><th>Input</th><th>Bit</th></tr><tr><td>0</td><td>16</td></tr><tr><td>1</td><td>17</td></tr><tr><td>2</td><td>18</td></tr></table></td></tr>
<tr><td>15-8
—</td><td>Reserved</td></tr>
<tr><td>7-0
FORCE_FILT</td><td>Force Filter
Specifies the count, in clock cycles, that a force input must remain at a given logic state before the filtered force input switches state.
0000_0000b - Bypass filter
All other values - Filter threshold</td></tr>
</table>

62.8.8 LC n Force Control (LC0_FCTRL - LC2_FCTRL)

Offset

Register	Offset
LC0_FCTRL	30h
LC1_FCTRL	70h
LC2_FCTRL	B0h

Function

Provides control of the force inputs.

7-0 MUXSEL	Mux Select Selects the source of the LC input. All LU_IN inputs go through a two-stage synchronizer, but the LU_OUT signals fed back to this mux do not have this two-stage delay because they are already synchronous to LCU clock. 0000_0000b - Logic 0 0000_0001b-0000_1100b - LU_IN0 to LU_IN11 0000_1101b-0001_1000b - LU_OUT0 to LU_OUT11 All other values are reserved.

62.8.11 Configuration (CFG)

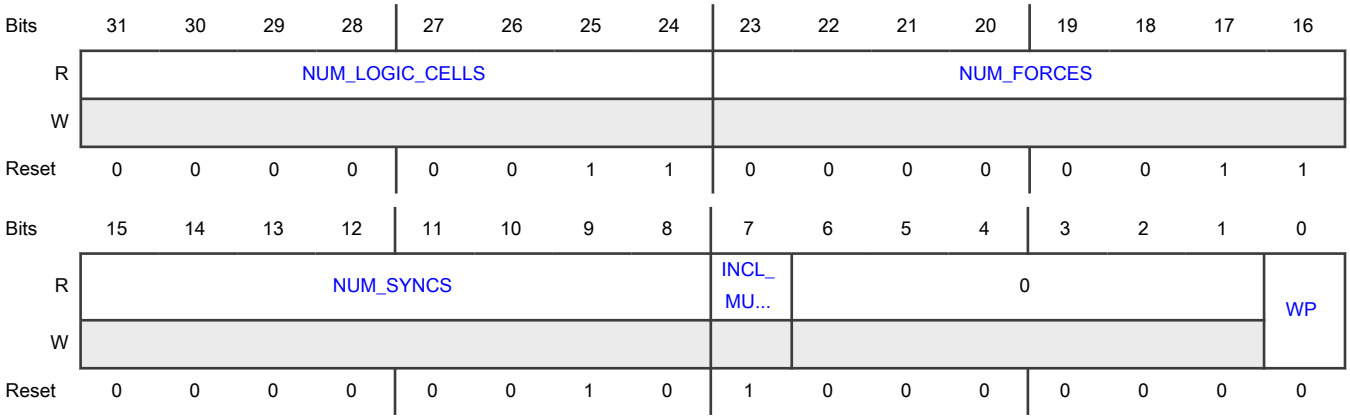
Offset

Register	Offset
CFG	280h

Function

Indicates the LCU configuration, and provides write protection.

Diagram



Fields

Field	Function
31-24 NUM_LOGIC_CELLS	LCs Indicates the number of LCs.
23-16 NUM_FORCES	Force Inputs Indicates the number of force inputs for each LC.
15-8 NUM_SYNCS	Sync Inputs Indicates the number of sync inputs for each LC.
7 INCL_MUXES	Input Muxing Indicates whether LCU supports input muxing. 0b - Not supported 1b - Supported
6-1 —	Reserved
0 WP	Write Protect Turns on write protection for all LCU registers except SWVALUE, LC*n*_STS, and FORCESTS. 0b - No effect 1b - Turn on write protection

62.8.12 Software Override Enable (SWEN)

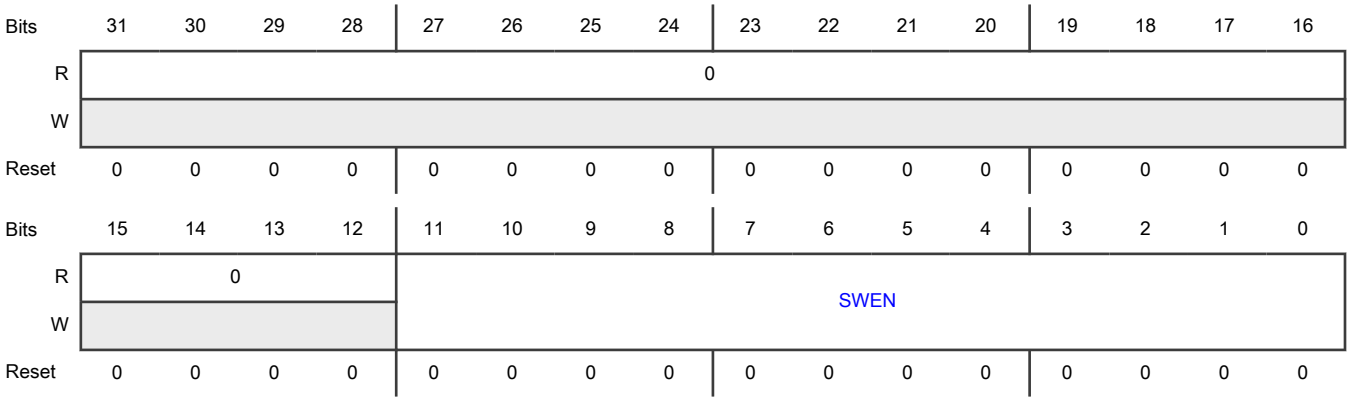
Offset

Register	Offset
SWEN	284h

Function

Enables overrides for LC inputs.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 SWEN	Software Override Enable Enables software override of LC inputs. For each bit: 0b - Disable 1b - Enable Mapping of bits: See Mapping of 12-bit input, output, and state fields.

62.8.13 Software Override Value (SWVALUE)

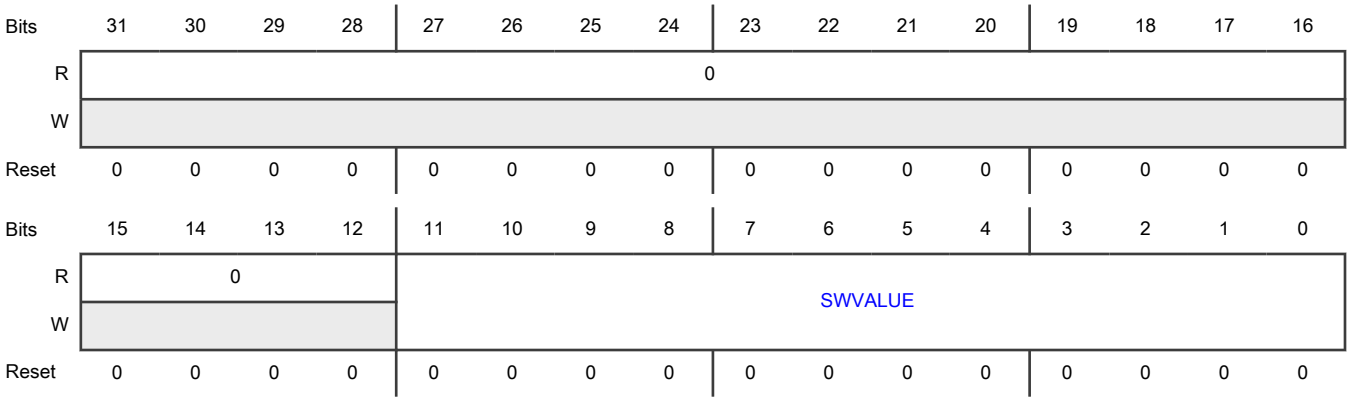
Offset

Register	Offset
SWVALUE	288h

Function

Specifies the software override value for each LC input.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 SWVALUE	Software Override Value Specifies the software override value for each LC input. For each bit: 0b - 0 1b - 1 Mapping of bits: See Mapping of 12-bit input, output, and state fields.

62.8.14 Output Enable (OUTEN)

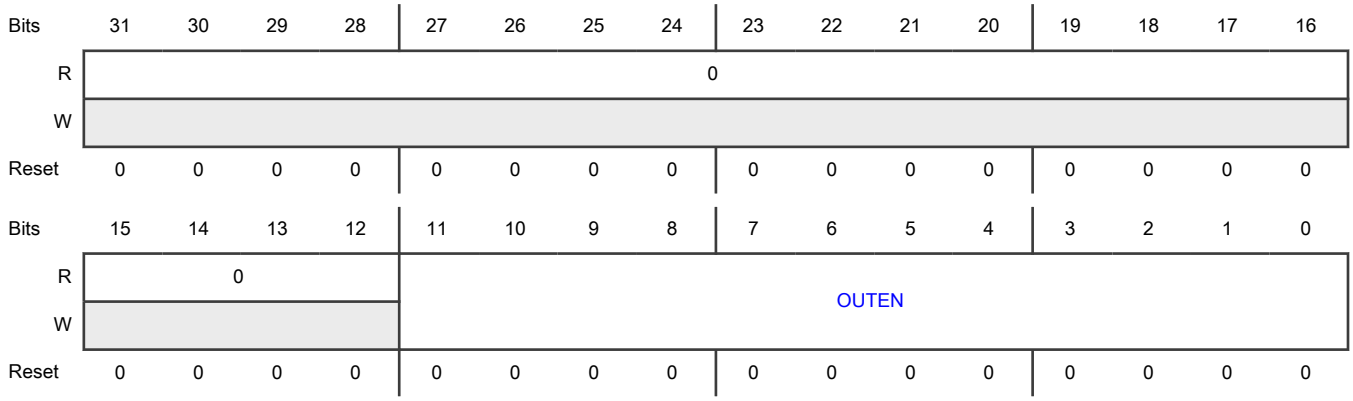
Offset

Register	Offset
OUTEN	28Ch

Function

Enables LC outputs.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 OUTEN	Output Enables Enables LC outputs. For each bit: 0b - Disable 1b - Enable Mapping of bits: See Mapping of 12-bit input, output, and state fields.

62.8.15 Logic Inputs (LCIN)

Offset

Register	Offset
LCIN	290h

Function

Indicates states of LC inputs.

If you write to this register, LCU generates a bus transfer error.

Diagram

62.8.16 Overridden Inputs (SWOUT)

Offset

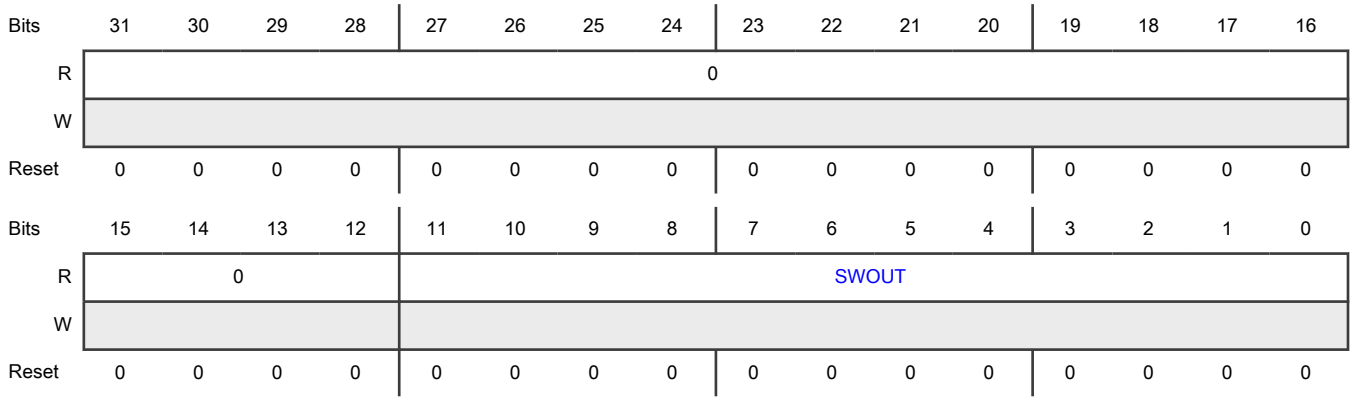
Register	Offset
SWOUT	294h

Function

Indicates states of LC inputs or states of software-overridden inputs, depending upon the state of the corresponding SWEN bit.

If you write to this register, LCU generates a bus transfer error.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 SWOUT	Overridden Inputs Indicates states of LC inputs or software-overridden inputs. For each bit, when the corresponding SWEN bit is 0: 0b - LC input is 0 1b - LC input is 1 For each bit, when the corresponding SWEN bit is 1: 0b - Software-overridden input is 0 1b - Software-overridden input is 1 Mapping of bits: See Mapping of 12-bit input, output, and state fields.

62.8.17 Logic Outputs (LCOUT)

Offset

Register	Offset
LCOUT	298h

Function

Indicates states of LC outputs.

If you write to this register, LCU generates a bus transfer error.

Diagram

Fields

Field	Function
31-12 —	Reserved
11-0 FORCESTS	Force Status Indicates the current force states of all LCs, mirrored from LC*n*_STS[FORCESTS]. Change these bits to 0 by writing 1 to them or to the corresponding bit in the specific LC*n*_STS register. This field allows you to simultaneously change FORCESTS bits to 0 across multiple LCs. For each bit: 0b - Not in force state 1b - Read: In force state — Write: Clear force state bit Mapping of bits: See Mapping of 12-bit input, output, and state fields.

62.8.20 Debug Mode Enable (DBGEN)

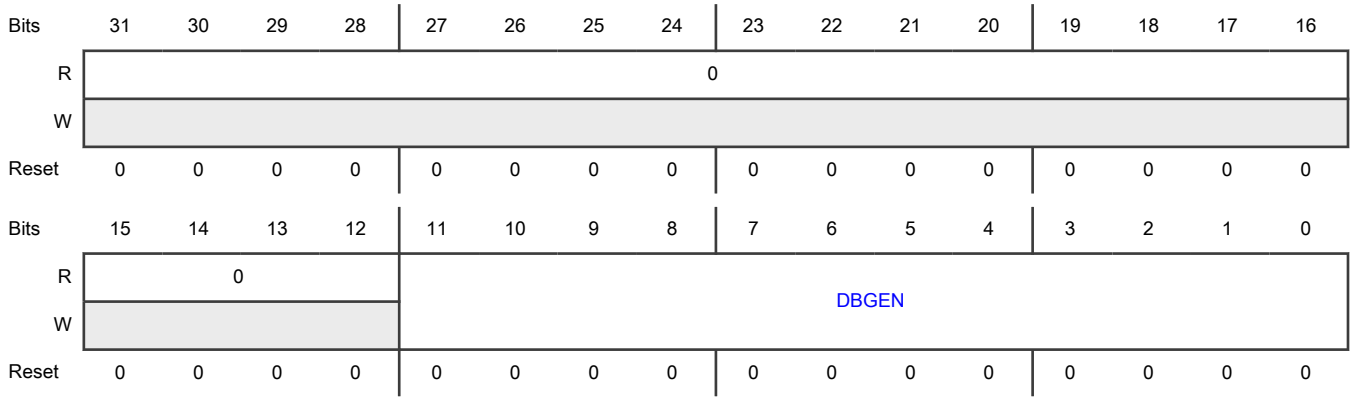
Offset

Register	Offset
DBGEN	2A8h

Function

Enables outputs to continue operation when the chip is in Debug mode.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 DBGEN	Debug Mode Enable Enables outputs to continue operation in Debug mode. For each bit: 0b - Debug mode inactive 1b - Debug mode active Mapping of bits: See Mapping of 12-bit input, output, and state fields.

Chapter 63
Enhanced Modular IO Subsystem (eMIOS)

63.1 Chip-specific eMIOS information

63.1.1 eMIOS configuration

This chip has up to three instances of eMIOS that are each configured as shown in the following tables.

Table 399. eMIOS instances

Instance	S32K314/S32K324/S32K344/ S32K358/S32K348/S32K338/S32K328/ S32K388/S32K389	S32K310/S32K311/S32K312/S32K322/ S32K342/S32K341
eMIOS_0	Yes	Yes
eMIOS_1	Yes	Yes
eMIOS_2	Yes	No

Table 400. eMIOS configuration

Parameter	eMIOS_0	eMIOS_1	eMIOS_2
Timer width	16 bits[1]	16 bits[1]	16 bits[1]
Number of channels	24	24	24
Channels configuration	See EMIOS channel configuration figure below		
Local Channel prescaler width	4	4	4
Number of global counter buses	2	2	2
Number of global prescaler	1	1	1
Global channel prescaler width	8	8	8

1. For S32K388/S32K389: 24 bits

NOTE

eMIOS is clocked by CORE_CLK.

63.1.2 Channel types

The eMIOS contain 4 different types of channel, which are listed below.

Table 401. eMIOS channel types

Mode Description	Name	Ch TypeX	Ch TypeY	Ch TypeG	Ch TypeH
General Purpose Input / Output	GPIO	X	X	X	X
Single Action Input Capture	SAIC	X	X	X	X

Table continues on the next page...

CH20	Y	Y	Y
CH21	Y	Y	Y

63.1.3 Channel configuration

The eMIOS channel configuration with respect to Type and Counter_bus is shown below.

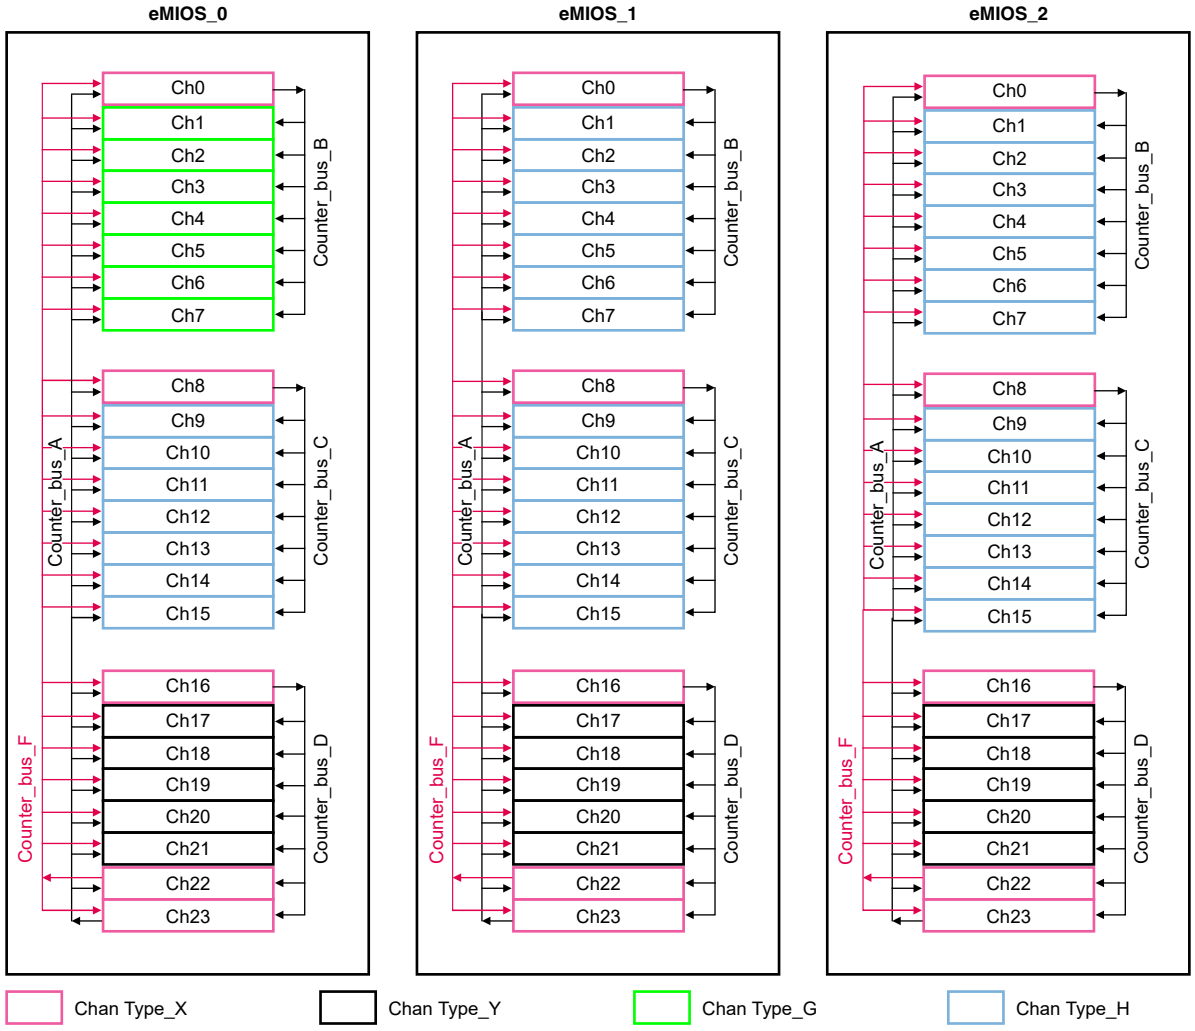

Figure 321. EMIOS channel types

63.1.4 eMIOS disabling

eMIOS can disable it's output using it's disable inputs. Disable inputs[3:0] are driven from the flag out bits[11:8].

Disable inputs	
eMIOS0 Output disable input[3:0]	trgmux_output[31:28]
eMIOS1 Output disable input[3:0]	trgmux_output[31:28]
eMIOS2 Output disable input[3:0]	trgmux_output[31:28]

For details, see the TRGMUX connectivity file attached to this document.

63.1.5 BCTU Interface

Each eMIOS channel, with the exception of the main counterbus channel (ch[23]) is capable of triggering the BCTU. See BCTU chapter for mapping. BCTU allows triggering from as many eMIOS modes as possible.

63.2 Introduction

eMIOS provides independent channels, UCs, that you configure to generate or measure time events for different functions in different chip applications.

eMIOS distributes these channels across a number of global and local counter buses. Each local bus is dedicated to a group of eight contiguous channels. Each channel can generate its own timebase, and each counter bus has its timebase provided by a dedicated channel. For a list of counter buses with their assigned channels and timebase sources, see Counter buses, channels, and timebase sources.

63.3 Block diagram

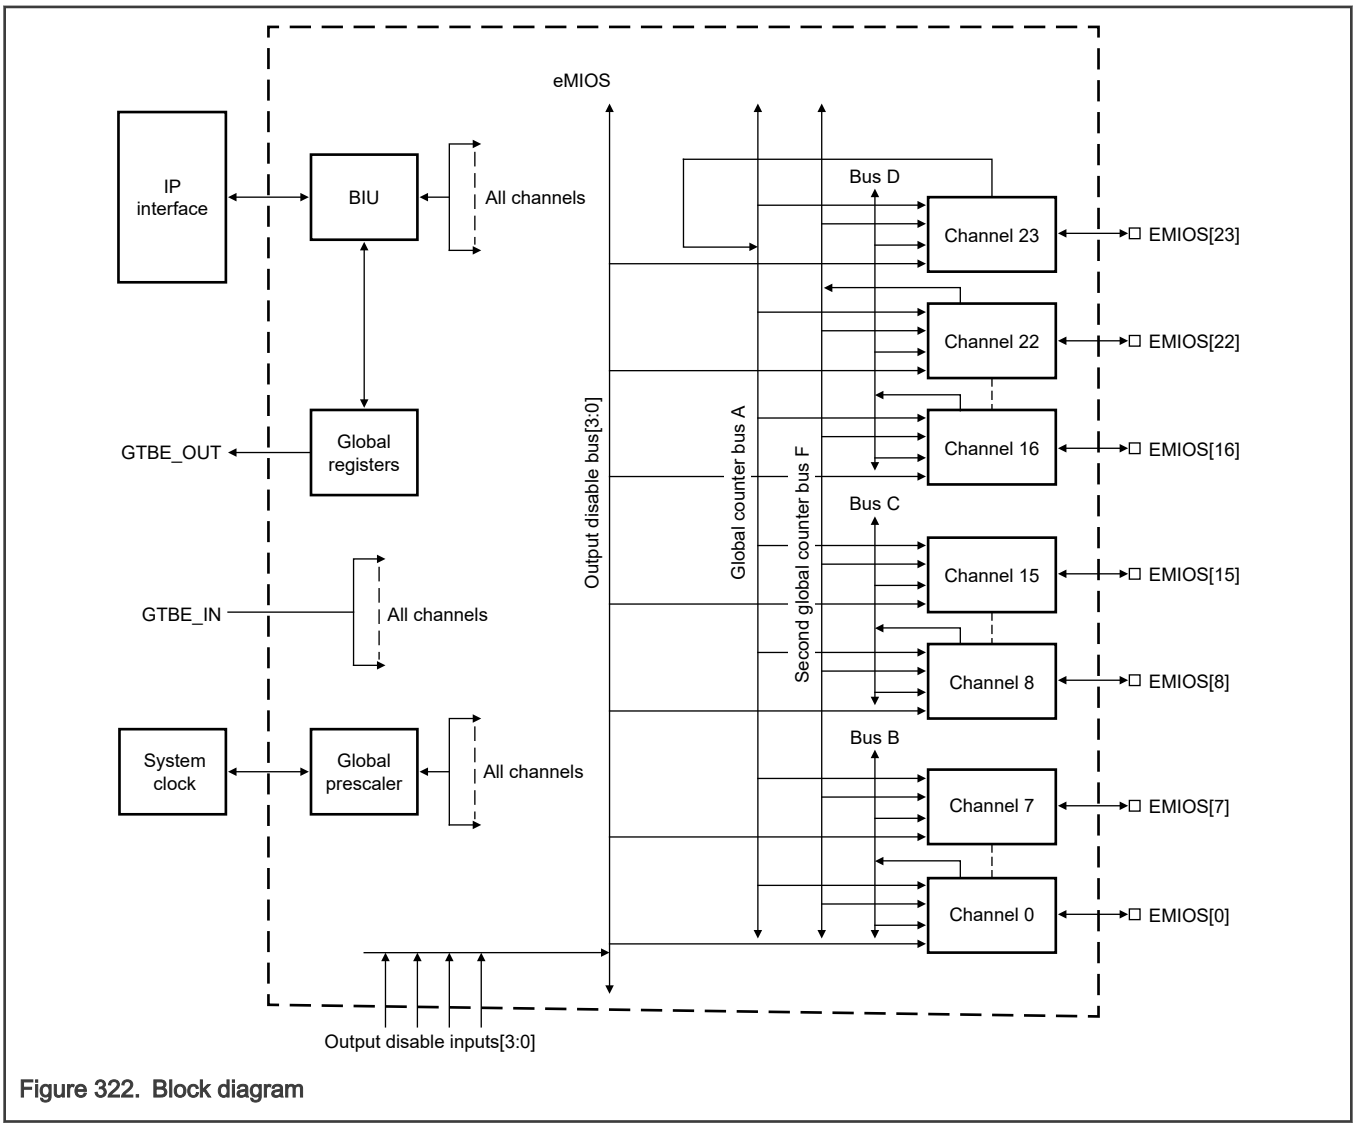

Figure 322. Block diagram

63.4 Features

- 24 UCs distributed across local counter buses as shown in Counter buses, channels, and timebase sources
- Global counter bus A driven by UC23
- Global counter bus F driven by UC22
- Synchronized timebases shared through the counter buses

- Dedicated timebase for each channel, distinct from the counter buses
- Global clock prescaler (GCP)
- One CP per channel
- Dedicated set of control and status registers for each UC
- 24-bit–wide data registers
- Shadow flag register (GFLAG) to access all channel flags with one read access
- Ability to freeze the UC state for debug purposes
- Motor control capability

63.5 Functional description

63.5.1 Reset

eMIOS resets asynchronously. Reset affects all registers.

On reset, UCs enter GPIO input mode.

63.5.2 Counter buses, channels, and timebase sources

Table 403. Counter buses, channels, and timebase sources

Counter bus	Channels	Timebase channel
Global bus A	All UCs	23
Local bus B	• UC0 • UC1 • UC2 • UC3 • UC4 • UC5 • UC6 • UC7	0
Local bus C	• UC8 • UC9 • UC10 • UC11 • UC12 • UC13 • UC14 • UC15	8
Local bus D	• UC16	16

Table continues on the next page...

Table 403. Counter buses, channels, and timebase sources (continued)

Counter bus	Channels	Timebase channel
	• UC17 • UC18 • UC19 • UC10 • UC21 • UC22 • UC23	
Global bus F	All UCs	22

63.5.3 Unified channels (UC)

63.5.3.1 Overview

Each UC contains the following:

- Two double-buffered data registers, A*n* and B*n*, that allow up to two events—input capture, output compare, or both—to occur before software intervention is needed
- Two comparators, A and B, that indicate when the selected counter bus is equal to the value in A*n* and B*n*
- An internal counter (CNT*n*[C]) that runs in all modes except GPIO.

  You can use this counter as a local timebase or to count input events. You can use it as a timebase if CNT*n*[C] is not used in the current mode.
- An output flip-flop that holds the logic level to be applied to the output pin
- A status register, UC Status n (S0 - S23), that flags input capture and match events, indicates flag overruns and overflows, and shows the input and output pin states
- A control register, UC Control n (C0 - C23), that controls UC operation

You control the following operational characteristics for each UC:

- The logic (C*n*[MODE]) that specifies the behavior of the UC (see UC modes)
- The counter bus (C*n*[BSL]) that provides the timebase for all timing functions
- The CP (C*n*[UCPRE] and C2_*n*[UCEXTPRE])
- The minimum input pulse width (C*n*[IF]) for the input filter that determines valid pin transitions
- Which input edges to detect (C*n*[EDSEL])
- Which of four output disable input signals (C*n*[ODISSL]) to use for disabling outputs
- For all output modes except GPIO, whether to disable the output flip-flop (C*n*[ODIS])

UC block diagram illustrates the basic UC architecture.

For a list of counter buses and their assigned channels and timebase sources, see Counter buses, channels, and timebase sources.

63.5.3.2 UC block diagram

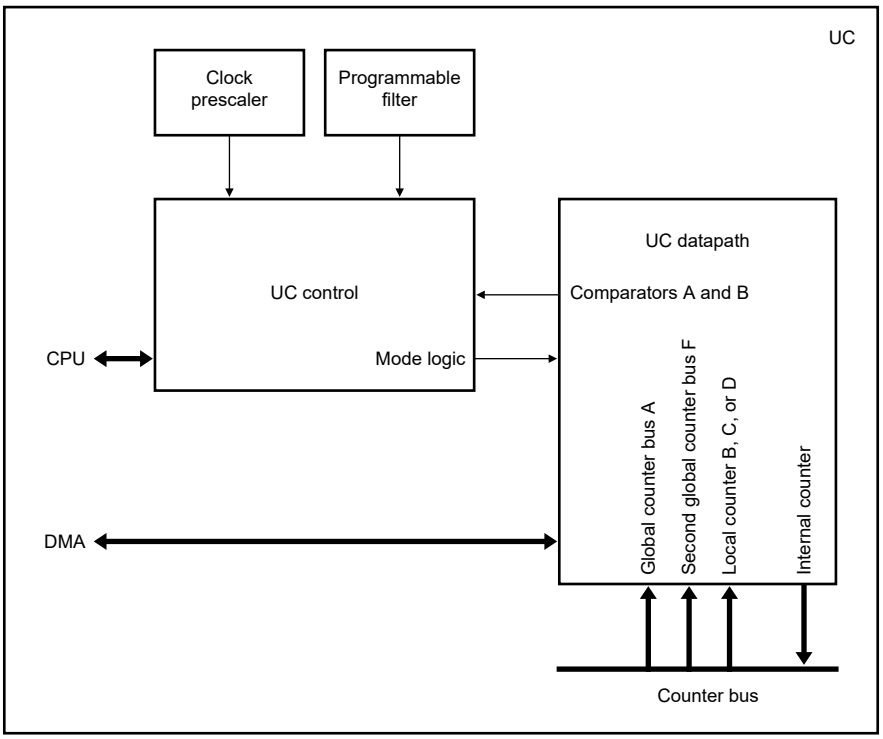

Figure 323. UC block diagram

63.5.3.3 Buffered modes

To provide smooth waveform generation even when A*n*[A] and B*n*[B] are changing, the following modes double buffer the A*n* and B*n* registers:

- Modulus Counter Buffered (MCB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Output PWM Buffered (OPWMB) mode

These modes appear in separate sections because there are several basic differences in UC operation between them and their corresponding nonbuffered modes.

63.5.3.4 UC control and datapath

As illustrated in UC control and datapath diagram, the UC contains control and datapath sub-blocks.

The control sub-block generates signals to control the multiplexers in the datapath sub-block. eMIOS implements each UC mode in dedicated logic independent from the other modes. The UC modes share a set of registers allowing the storing of sequential events.

The datapath block contains the channel A and B registers, the internal timebase, and the comparators. Multiplexers receive inputs from the control sub-block to configure the datapath for the specific channel modes. This configuration consists of selecting the input of comparators and data for the register inputs. The outputs of the A and B comparators connect to the control block.

63.5.3.5 UC control and datapath diagram

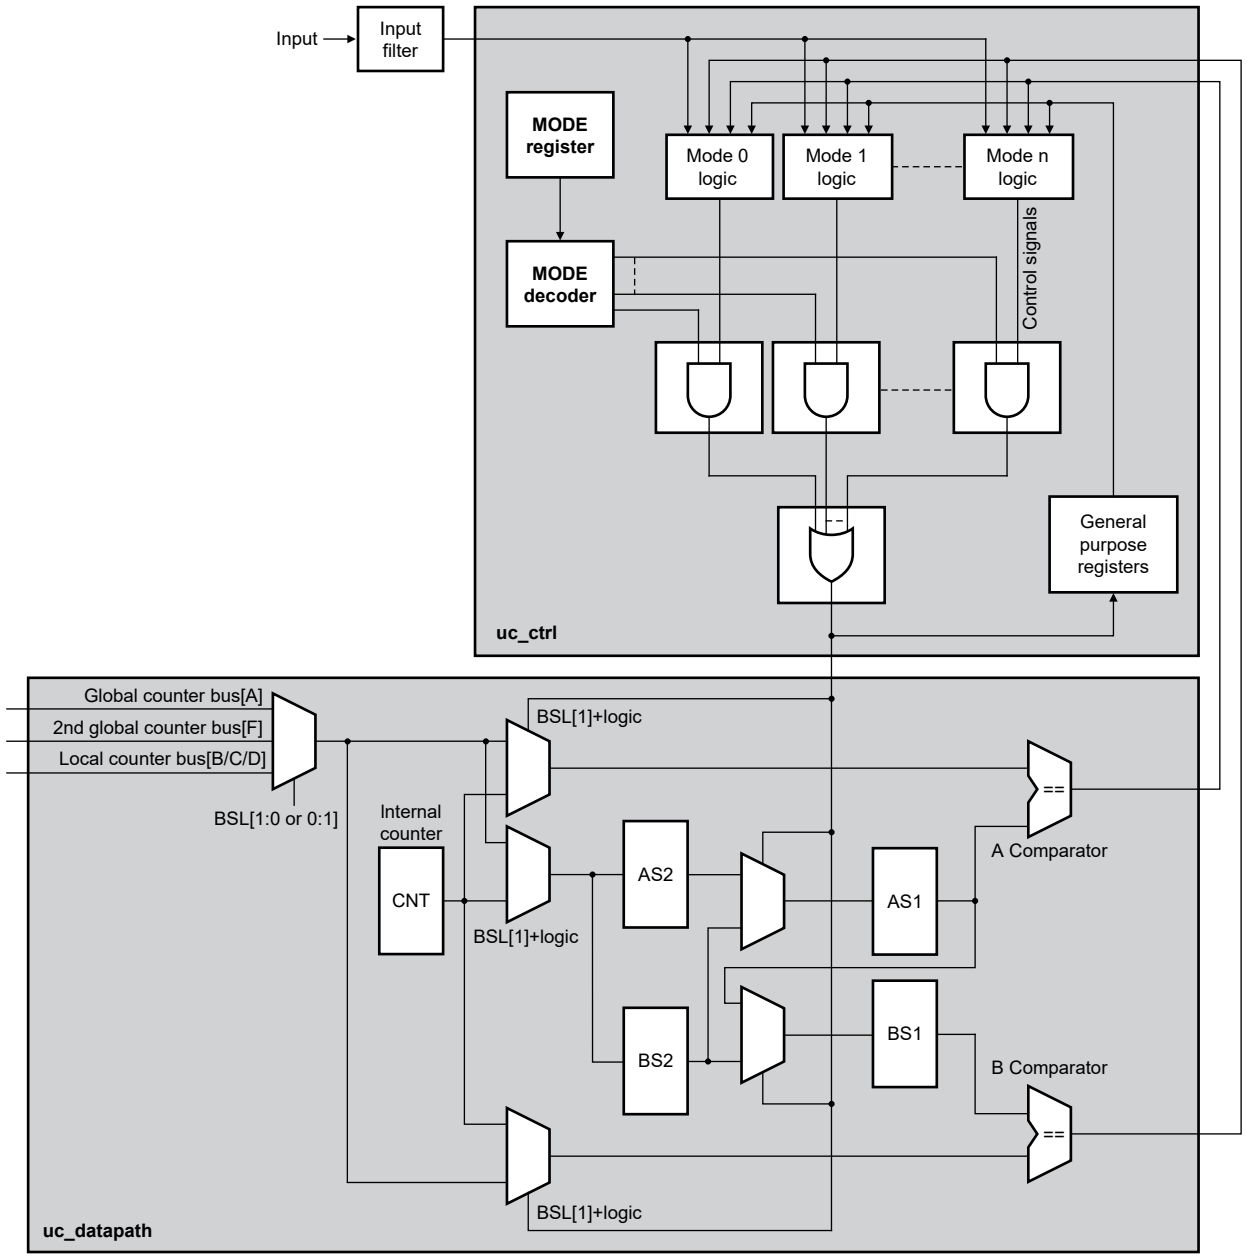

Figure 324. UC control and datapath diagram

63.5.3.6 UC modes

You can configure UCs to operate in the following modes:

- General-Purpose Input and Output (GPIO) mode
- Single Action Input Capture (SAIC) mode
- Single Action Output Capture (SAOC) mode
- Input Pulse Width Measurement (IPWM) mode
- Input Period Measurement (IPM) Mode

- Double Action Output Compare (DAOC) mode
- Pulse Edge Counting (PEC) mode
- Modulus Counter (MC) mode
- Modulus Counter Buffered (MCB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode
- Output PWM Buffered (OPWMB) mode
- Output PWM with Trigger (OPWMT) mode

Each channel supports a specific subset of these modes. See the chip-configuration information to see which modes each channel supports.

63.5.3.7 General-Purpose Input and Output (GPIO) mode

63.5.3.7.1 Overview

This mode disables all UC input-capture and output-compare functions, and resets and disables the internal counter (C*n*[C]). All control fields remain accessible.

To change the UC from one operation mode to another, you must first change to GPIO mode and then change to the desired final mode. To prepare the UC for a new operation mode, you must configure AS1, BS1, AS2, and BS2 before exiting GPIO mode and entering the desired final mode (see AS1, AS2, BS1, and BS2 shadow registers). Specifically:

- Writing to A*n*[A] stores the same value in AS1 and AS2.
- Writing to B*n*[B] stores the same value in BS1 and BS2.
- Writing to ALTA*n*[ALTA] stores a value only in AS2.

As its name implies, GPIO mode supports both input and output submodes. See Differences for input and output submodes.

63.5.3.7.2 Differences for input and output submodes

Table 404. Differences for input and output submodes

Submode	To enter submode, write this value to C*n*[MODE]	Characteristics
Input	0	• You control the generation of input-capture flags with C*n*[EDPOL] and C*n*[EDSEL]. • You can determine the input pin status by reading S*n*[UCIN].
Output	1	• The UC performs as a single output port pin. • The value of C*n*[EDPOL] permanently drives the output flip-flop.

63.5.3.8 Single Action Input Capture (SAIC) mode

63.5.3.8.1 Overview

In this mode, when a triggering event occurs on the input pin, eMIOS:

- Captures the selected timebase into AS2
- Changes S*n*[FLAG] to 1 to indicate that an input capture has occurred

A*n*[A] returns the value of AS2. As soon as the UC enters SAIC mode after exiting GPIO mode, the channel is ready to capture events.

eMIOS captures the events as soon as they occur. Therefore, reading A*n*[A] always returns the value of the latest captured event. Subsequent capture events occur regardless of whether you read the previous event from A*n*[A]. Each new capture event sets the input capture flag (writes 1 to S*n*[FLAG]).

The input capture is triggered by an edge transition on the input pin as configured by C*n*[EDPOL] and C*n*[EDSEL].

SAIC with rising edge triggering and SAIC with both edges triggering show how to use the UC for input capture.

63.5.3.8.2 SAIC submodes and MODE field values

Table 405. SAIC submodes and MODE field values

Capture behavior	C*n*[MODE] (binary)
The UC only captures the timestamp.	000_0010
• The UC captures a timestamp. • AS2 bit 31 indicates the input signal level.	100_0010

63.5.3.8.3 Effect of C*n*[EDPOL] on edge capturing

Table 406. Effect of C*n*[EDPOL] on edge capturing

C*n*[EDPOL]	Input signal transition	Resulting value of AS2 bit 31
0	0→1	0
	1→0	1
1	0→1	1
	1→0	0

63.5.3.8.4 SAIC with rising edge triggering

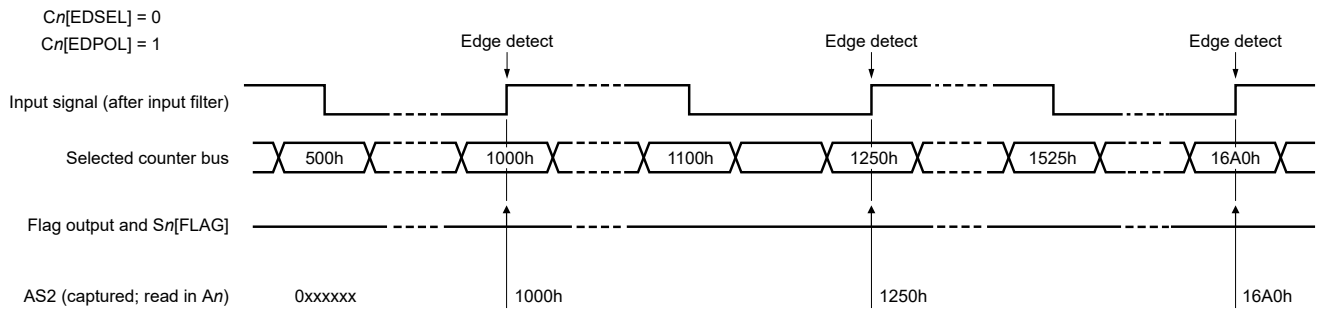

Figure 325. SAIC with rising edge triggering

63.5.3.8.5 SAIC with both edges triggering

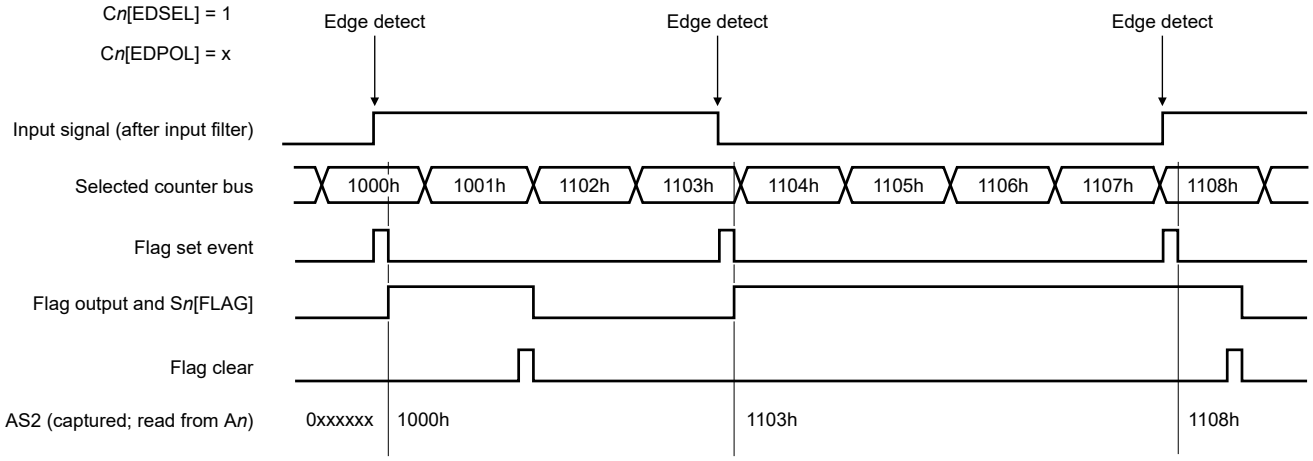

Figure 326. SAIC with both edges triggering

63.5.3.9 Single Action Output Capture (SAOC) mode

63.5.3.9.1 Overview

In this mode, eMIOS loads a match value into AS2 and then immediately transfers it to AS1 for comparison with the selected timebase. When an output-compare match occurs, eMIOS:

- Either toggles the output flip-flop or transfers C*n*[EDPOL] to the output flip-flop, as determined by C*n*[EDSEL].
- Sets the input capture flag (changes S*n*[FLAG] to 1).

Along with the match, S*n*[FLAG] becomes 1 to indicate that the output-compare match has occurred. Writing to A*n*[A] stores the value in AS2, and reading A*n*[A] returns the AS1 value.

The channel internal counter in SAOC mode is free-running. It starts counting as soon as the UC enters SAOC mode.

You can force an output-compare match by writing 1 to C*n*[FORCMA]. A forced output-compare match does not set the input capture flag (S*n*[FLAG]).

When the UC enters SAOC mode after exiting GPIO mode, the output flip-flop value becomes the complement of C*n*[EDPOL].

You select the internal or external counter bus with C*n*[BSL].

SAOC with C*n*[EDPOL] transferred to the output flip-flop shows how to perform a single output compare and transfer C*n*[EDPOL] to the output flip-flop.

SAOC toggling the output flip-flop shows how to perform a single output compare and toggle the output flip-flop at each match.

63.5.3.9.2 Preload the desired match value

eMIOS enables matches immediately after the UC enters SAOC mode. Therefore, you must write the desired match value to AS1 before the UC enters SAOC mode. You can update AS1 at any time. This modifies the match value reflected in the channel-generated output signal. Subsequent capture events occur regardless of whether you write to A*n*[A] again. Each new capture event sets the input capture flag (S*n*[FLAG]). See SAOC with flag behavior.

63.5.3.9.3 SAOC with C*n*[EDPOL] transferred to the output flip-flop

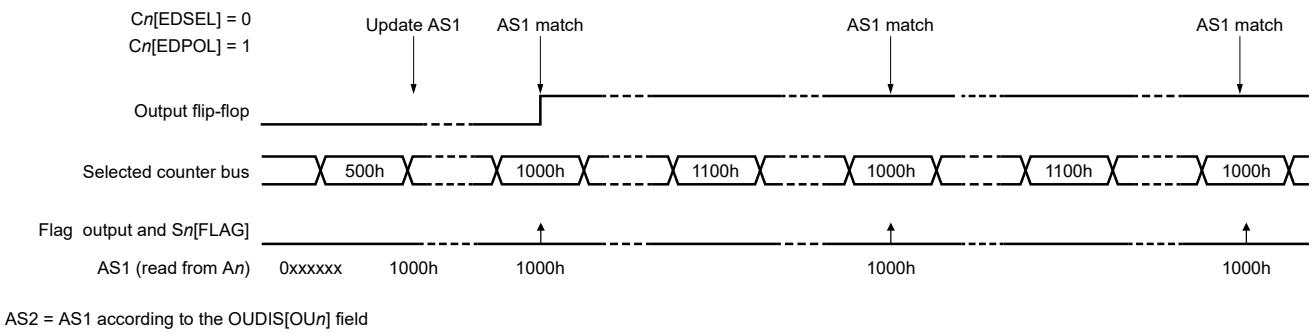

Figure 327. SAOC with C*n*[EDPOL] transferred to the output flip-flop

63.5.3.9.4 SAOC toggling the output flip-flop

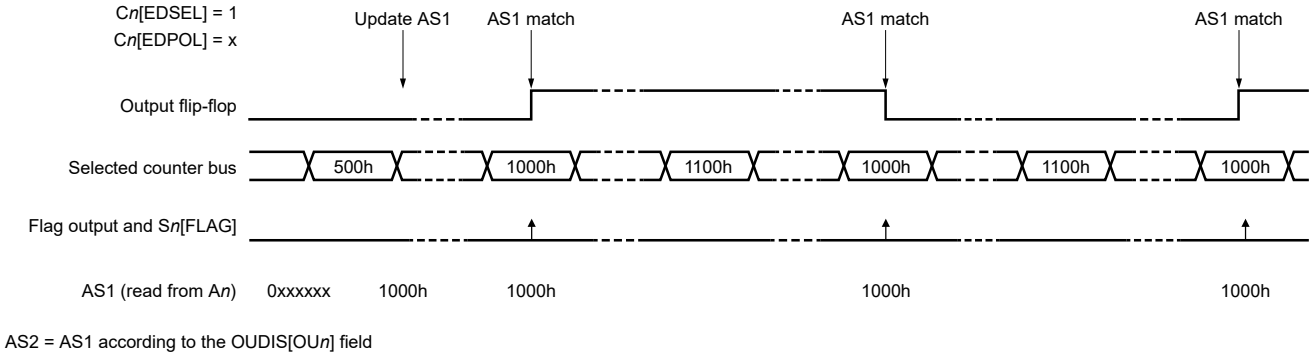

Figure 328. SAOC toggling the output flip-flop

63.5.3.9.5 SAOC with flag behavior

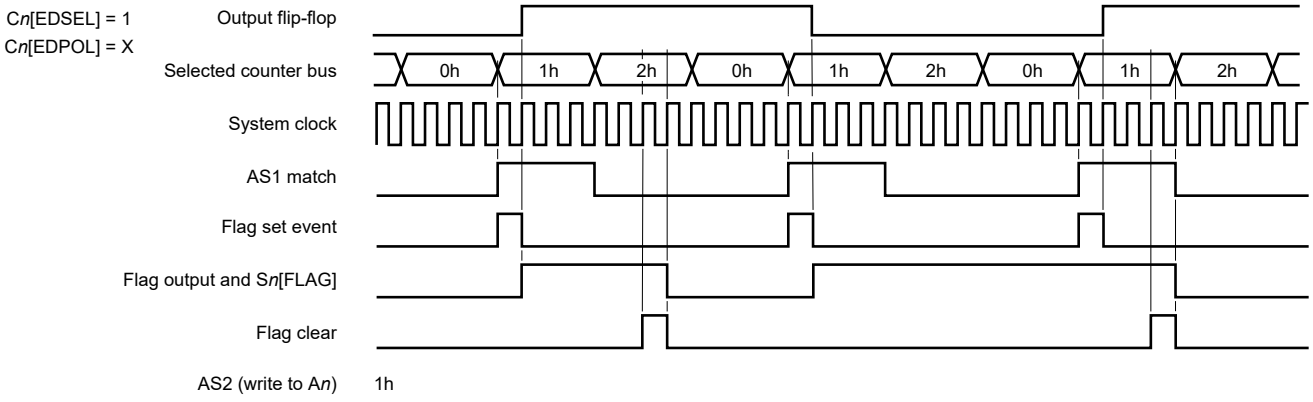

Figure 329. SAOC with flag behavior

63.5.3.10 Input Pulse Width Measurement (IPWM) mode

63.5.3.10.1 Overview

This mode allows you to measure the width of a positive or negative pulse. Select whether to measure from the rising or falling edge with Edge Polarity (Cn[EDPOL]).

The first leading edge:

- Triggers the first input capture, which latches the count value of the selected timebase into BS2 (see AS1, AS2, BS1, and BS2 shadow registers)
- Does not set the input-capture flag (Sn[FLAG])
- Enables AS2 capture

The next trailing edge:

- Latches the selected timebase into AS2
- Sets the input-capture flag (Sn[FLAG])
- Transfers BS2 to BS1 and AS1

eMIOS captures successive values on consecutive edges of opposite polarity. If you initiate subsequent input capture events while the input-capture flag (Sn[FLAG]) is set, eMIOS updates AS2, BS1, and AS1 with the latest captured values and keeps the flag set.

63.5.3.10.2 Coherency

Reading A*n*[A] updates BS1 with AS1. It also disables transfers from BS2 and BS1 until the next read of B*n*[B].

Reading Bn updates BS1 with AS1. It also re-enables transfers from BS2 to BS1, which takes effect at the next trailing edge capture.

Because transfers from BS2 to AS1 are never blocked, to guarantee data coherency you must read An, then read Bn.

If you do not require coherent data, you should read Bn before you read An, although doing so requires a second read of Bn to unblock BS1 updates.

63.5.3.10.3 Timing example: measure pulse width

This figure shows how to measure the input pulse width by subtracting BS1 from AS2.

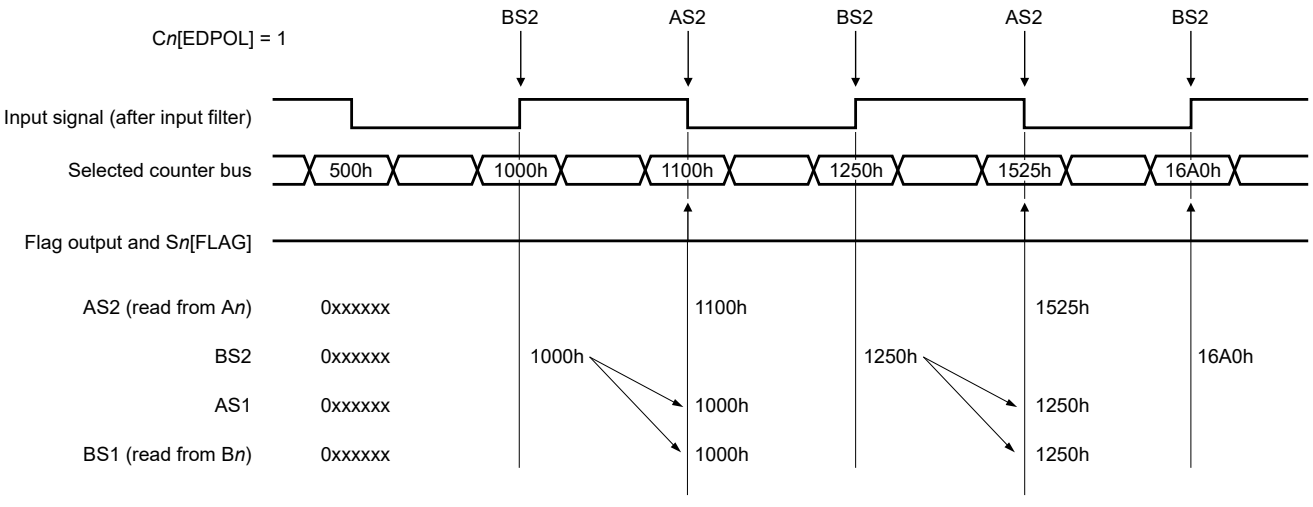

Figure 330. Timing example: measure pulse width

63.5.3.10.4 Timing example: AS1 and BS1 updates on channel reads

This example illustrates AS1 and BS1 updates when you read A*n*[A] and B*n*[B]. AS1 always has coherent data related to AS2 (see Coherency).

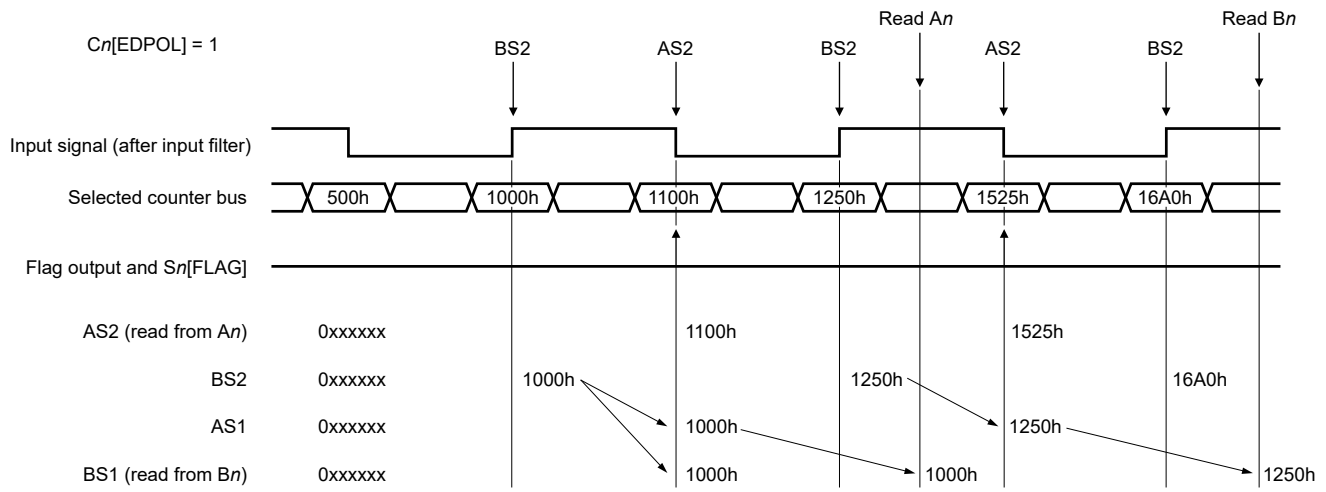

Figure 331. Timing example: BS1 and AS1 updates on channel reads

63.5.3.11 Input Period Measurement (IPM) Mode

63.5.3.11.1 Overview

This mode allows you to measure the period of an input signal. Select whether to measure from the rising or falling edges with Edge Polarity (C*n*[EDPOL]).

The first edge of selected polarity:

- Latches the selected timebase into AS2 and BS2 (see AS1, AS2, BS1, and BS2 shadow registers)
- Transfers BS2 to BS1
- Does not set the input-capture flag (S*n*[FLAG])

The second edge of the same polarity:

- Latches the counter bus value into AS2 and BS2
- Transfers BS2 to BS1 and AS1
- Sets the input-capture flag (S*n*[FLAG])

eMIOS repeats this process for each subsequent capture.

eMIOS captures successive values on two consecutive edges of the same polarity. The measured input signal must have a period of at least four system clock cycles to be properly captured by the synchronization logic at the channel input, even if the input filter is in bypass mode.

63.5.3.11.2 Coherency

Reading A*n*[A] updates BS1 with AS1, which provides coherent data in AS2 and BS1 (see Timing example: AS1 and BS1 updates on channel reads). It also disables transfers from BS2 and BS1 until the next read of B*n*[B].

Reading B*n*[B] updates BS1 with AS1. It also re-enables transfers from BS2 to BS1, which takes effect at the next edge capture.

63.5.3.11.3 Timing example: measure input period

This example illustrates how to measure the input period by subtracting BS1 from AS2.

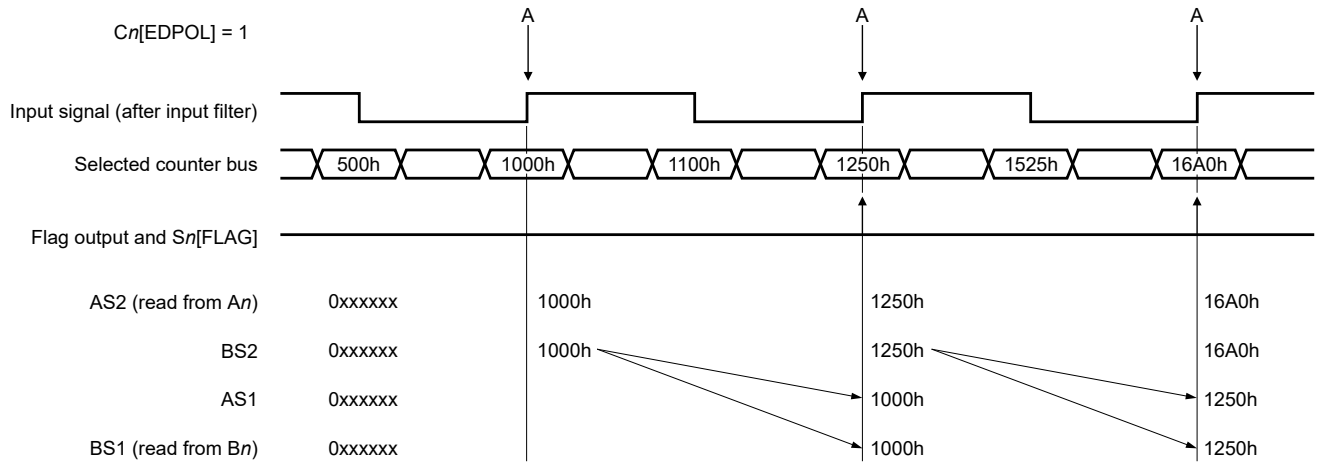

Figure 332. Timing example: measure input period

63.5.3.11.4 Timing example: AS1 and BS1 updates on channel reads

This diagram illustrates AS1 and BS1 updates when you read An[A] and Bn[B].

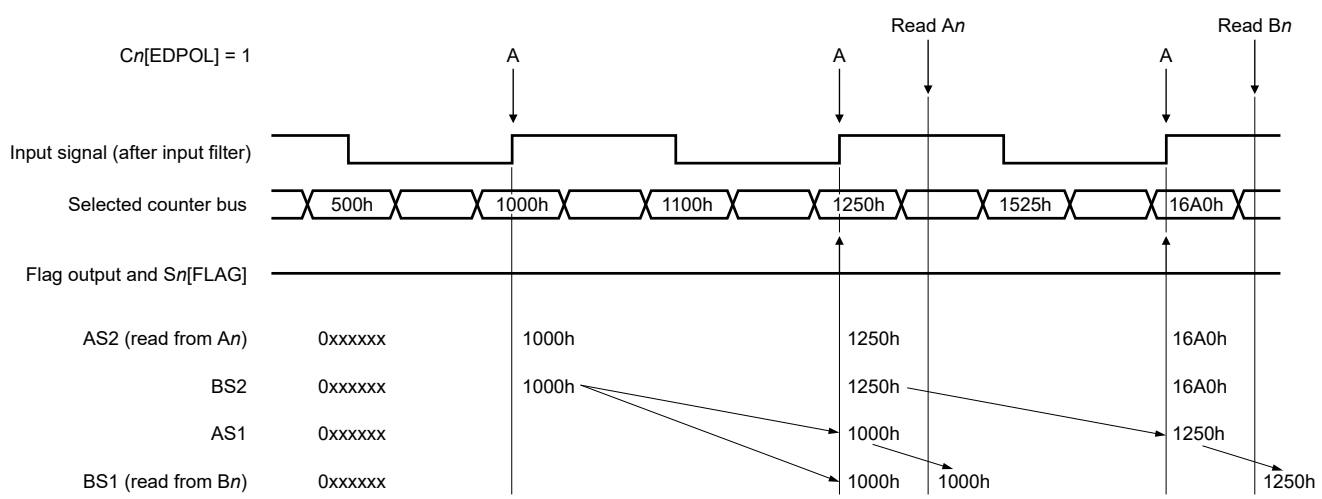

Figure 333. Timing example: AS1 and BS1 updates on channel reads

63.5.3.12 Double Action Output Compare (DAOC) mode

63.5.3.12.1 Overview

In this mode, matches on comparators A and B cause the UC to generate the leading and trailing edges of the variable pulse width output. See DAOC submodes and MODE field values. There is no restriction on the order in which A and B matches occur.

When the UC enters DAOC mode from GPIO mode, eMIOS disables both comparators and drives the complement of Edge Polarity (Cn[EDPOL]) onto the output flip-flop.

63.5.3.12.2 DAOC submodes and MODE field values

Table 407. DAOC submodes and MODE field values

When set flag event occurs	C*n*[MODE] (binary)
Only on B matches	000_0110
On A or B matches	000_0111

63.5.3.12.3 Data transfer and compare

If you enable output (write 0 to OUDIS[OU*n*]), on the next clock cycle the UC transfers AS2 and BS2 to AS1 and BS1 respectively (see Timing example: leading dead time insertion). If you disable output (write 1 to OUDIS[OU*n*]), no transfer occurs.

eMIOS enables and disables the A and B comparators independently. It enables comparator A only after the transfer to AS1 completes, and disables comparator A on the next A match. Similarly, eMIOS enables comparator B only after the transfer to BS1 completes, and disables comparator B on the next B match.

When a match occurs on comparator A, the output flip-flop acquires the value of Edge Polarity (C*n*[EDPOL]). When a match occurs on comparator B, the output flip-flop acquires the complement of Edge Polarity (C*n*[EDPOL]).

63.5.3.12.4 Differences between flag on A match and flag on A and B matches

In the flag on B match submode (see DAOC submodes and MODE field values), the UC sets the input-capture flag (S*n*[FLAG]) only for matches on the B comparator. In the flag on both A and B matches submode, it sets the flag for matches on either comparator.

If subsequent enabled output compares occur on AS1 or BS1, the UC continues generating pulses regardless of the flag state.

If you load both AS1 and BS1 with the same value, the B match takes precedence and the UC drives the complement of Edge Polarity (C*n*[EDPOL]) onto the output flip-flop.

63.5.3.12.5 Forced operation by Cn[FORCMA] and Cn[FORCMB]

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to the comparator, Edge Polarity (C*n*[EDPOL]) for an A match, or the complement of Edge Polarity for a B match. The force-match operations do not set the input-capture flag (S*n*[FLAG]).

63.5.3.12.6 Timing example: flag on both matches

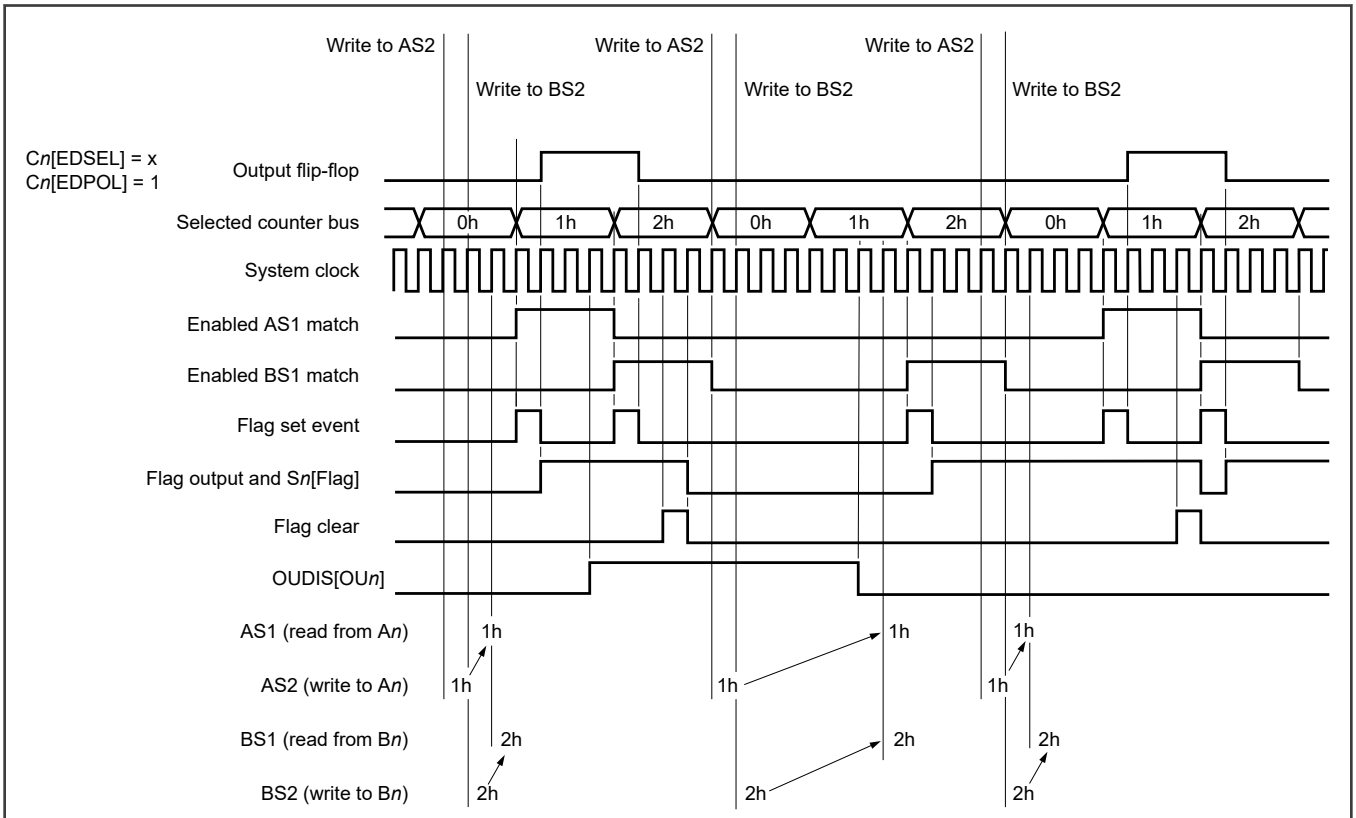

Figure 336. Timing example: transfer disabling

63.5.3.13 Pulse Edge Counting (PEC) mode

63.5.3.13.1 Overview

This mode counts the number of pulses or edges detected on the input for a desired time window. C*n*[EDSEL] and C*n*[EDPOL] determine which edges the UC counts.

Specify the window start time in AS1 and the end time in BS1. After you write to AS1, when the selected timebase matches comparator A, eMIOS resets the internal counter and starts counting input events. When the timebase matches comparator B, eMIOS:

- Disables the internal counter.
- Transfers the counter's content to AS2.
- Sets the input-capture flag (changes S*n*[FLAG] to 1).

You obtain the number of detected pulses by reading C*n*[C] or AS2.

Timing example continuous and Timing example single-shot show how to use the UC in continuous or single-shot operation.

63.5.3.13.2 PEC submodes and MODE field values

Table 408. PEC submodes and MODE field values

Operation	C*n*[MODE] (binary)
Continuous; the next match between comparator A and the selected timebase resets the internal counter and enables counting again. To guarantee coherent measurements when you read C*n*[C] after S*n*[FLAG] becomes 1, you must check if the timebase value is out of the time interval defined by AS1 and BS1. Alternately, AS2 (available in ALTA*n*[ALTA]) always holds the latest available measurement, providing coherent data at any time after the first set-flag event.	000_1010
Single-shot; The next match between comparator A and the selected timebase has no effect until you write to A*n*[A]. eMIOS also transfers the C*n*[C] value to AS2 when a match in the B comparator occurs.	000_1011

63.5.3.13.3 Timing example continuous

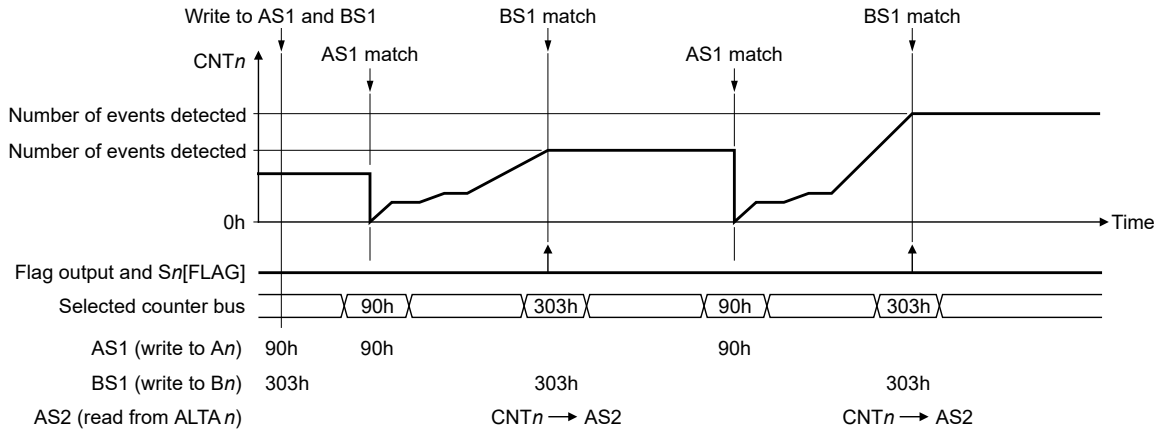

Figure 337. Timing example continuous

63.5.3.13.4 Timing example single-shot

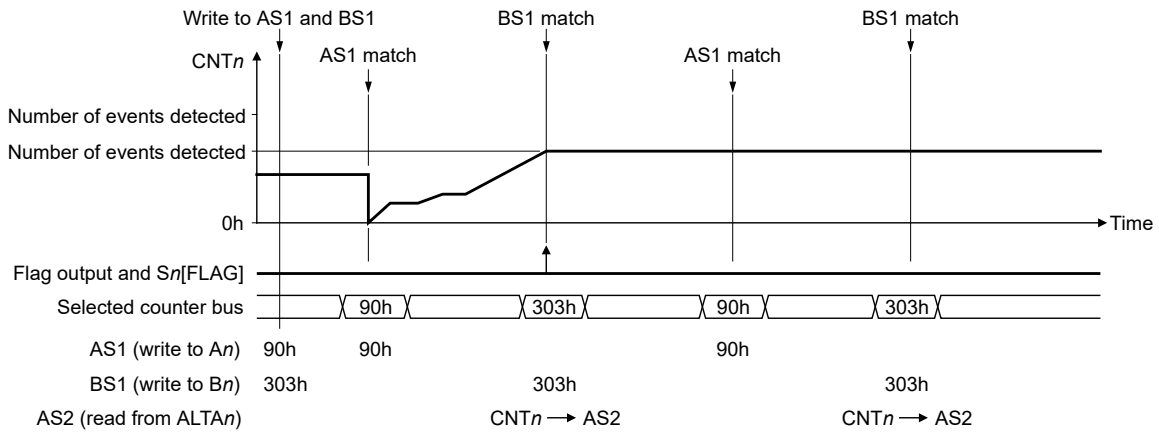

Figure 338. Timing example single-shot

63.5.3.14 Modulus Counter (MC) mode

63.5.3.14.1 Overview

In this mode, the UC produces a timebase for a counter bus or as a general purpose timer. The internal counter (C*n*[C]) counts up from the current value until it matches AS1.

Selecting external clock source (see MC submodes and MODE field values) causes the UC to uses the input signal pin as the source. You select the triggering polarity edge using Edge Polarity (C*n*[EDPOL]) and Edge Select (C*n*[EDSEL]).

You must write only non-zero values to A*n*[A]. Writing to A*n*[A] or the internal counter may cause a match to be missed and the counter to roll over and resume operation in the next cycle. The channel writes 0 to BS1, which is not accessible by the MCU. You can read and write BS2, but it is not used in this mode.

63.5.3.14.2 MC submodes and MODE field values

Table 409. MC submodes and MODE field values

Submode or function	C*n*[MODE] (binary)
Internal clock source	001_0pp0[1]
External clock source	001_0pp1[1]
Internal counter reset on match start	001_0p0p[1]
Internal counter reset on match end	001_0p1p[1]
Up Count	001_00pp[1]
Up Count-Down Count	001_01pp[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

63.5.3.14.3 Up Count submode

Table 410. Up Count submode operation

Counter reset timing[1]	C*n*[MODE]		
	Bit 1	External clock (Bit 0 = 1)	Internal clock (Bit 0 = 0)
Reset on match start	0	When the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]). • Increments the internal counter at the next input event, resulting in a short zero count.	When the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]). • Maintains the internal counter at 0 on the next prescaler tick after the match. • Resumes counting on the next prescaler tick.
		See Timebase with the fastest prescaler ratio and Timebase generation with clear on match start and internal clock.	
Clear on match end	1	When the next input event after the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]).	When the next internal counter tick after the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]).
		See Timebase with the fastest prescaler ratio and Timebase generation with clear on match end.	

1. If you select internal clock source and a prescaler value of 1 for the internal counter, the behavior is the same for both submodes.

See Timing example: Up Count submode.

63.5.3.14.4 Timing example: Up Count submode

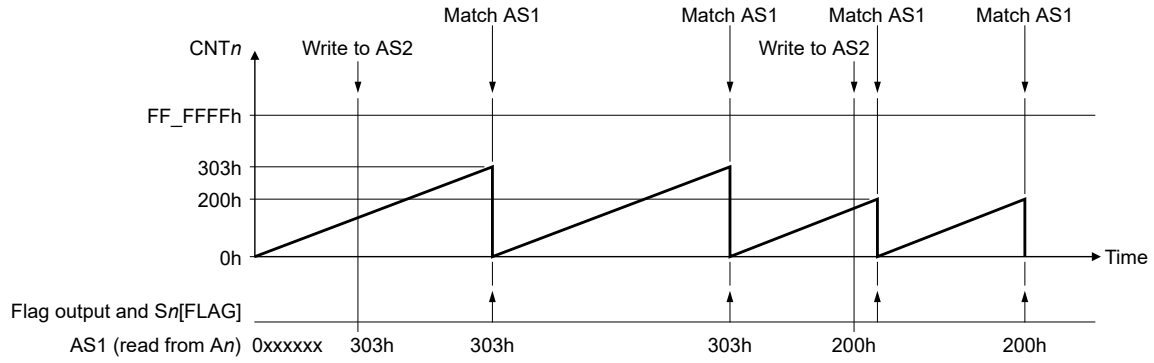

Figure 339. Timing example: Up Count submode

63.5.3.14.5 Up Count-Down Count submode operation

In Up Count-Down Count submode:

- When the internal counter matches AS1, the counter begins decrementing and the UC sets the input-capture flag (S*n*[FLAG]).
- When the internal counter matches BS1, the counter begins incrementing and, if in clear on match end operation (C*n*[1] = 1), the UC sets the input-capture flag (S*n*[FLAG]).

See Timing example: Up Count-Down Count submode.

63.5.3.14.6 Timing example: Up Count-Down Count submode

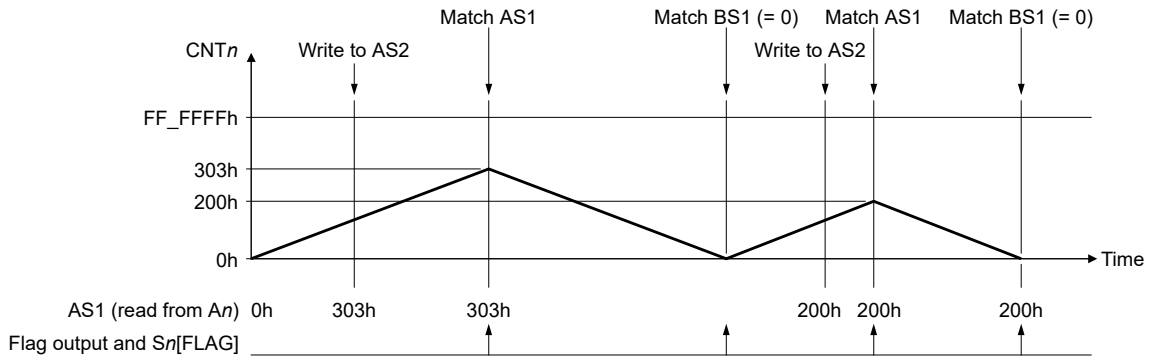

Figure 340. Timing example: Up Count-Down Count submode

63.5.3.14.7 Up Count with delayed reload operation

When the internal counter matches AS1 in the Up Count submode or BS1 in the Up Count-Down Count submode, the UC asserts the counter bus reload signal. You can read the counter bus reload signal in the following modes:

- Output PWM Buffered (OPWMB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

You can use the Reload Signal Output Delay Interval (C2*n*[UCRELDEL_INT]) to cause the UC to assert the reload signal only after a specified number of match events (from 2 to 32).

See Timing example: Up Count mode with delayed reload.

63.5.3.14.8 Timing example: Up Count mode with delayed reload

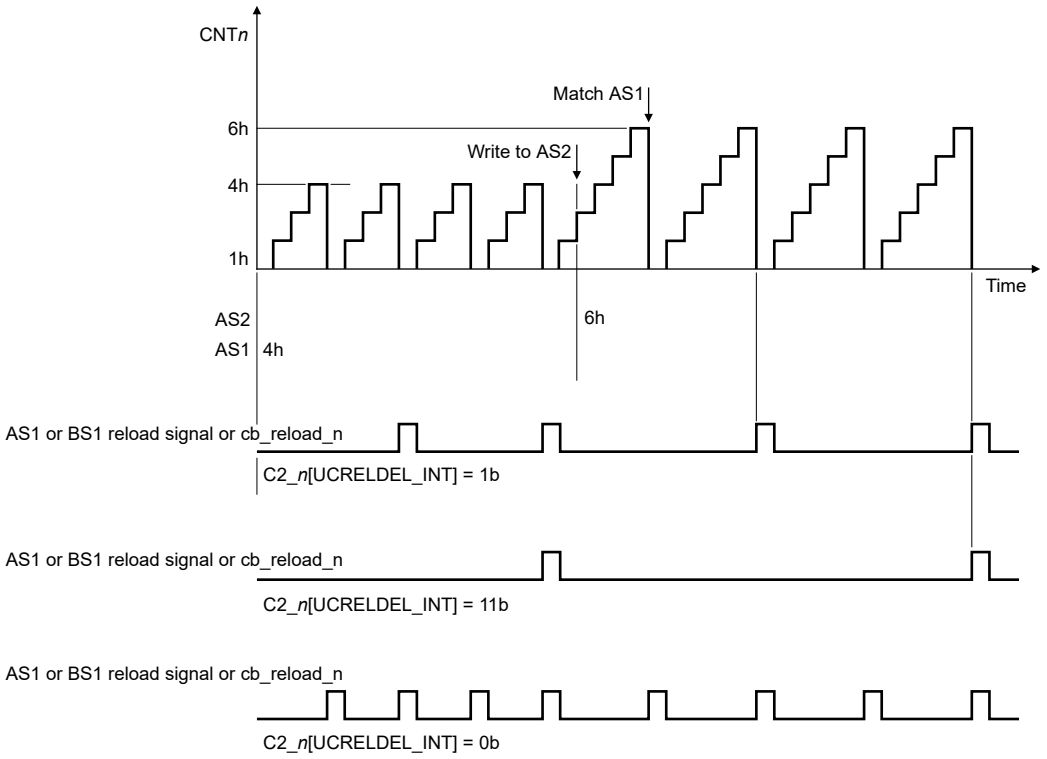

Figure 341. Timing example: Up Count mode with delayed reload

63.5.3.15 Modulus Counter Buffered (MCB) mode

63.5.3.15.1 Overview

In this mode, the UC generates a timebase that can be shared with other channels through the internal counter buses. AS1 is double-buffered, so you can change AS2 at any time with smooth transitions. The UC updates AS1 at the counter period boundary, which is when the internal counter (CNT*n*[C]) transitions to 1h.

Selecting external clock (see MCB submodes and MODE field values) causes the UC to use the input signal as the source. You select the triggering edge with Edge Polarity (C*n*[EDPOL]) and Edge Select (C*n*[EDSEL]).

You must ensure the internal counter is in the range from 1h to the AS1 value; otherwise, the A*n*[A] match does not occur and this causes the internal counter to wrap at the maximum counter value (FF_FFFFh for a 24-bit counter). After a counter wrap occurs, the UC resets the counter to 1h and resumes normal operation.

NOTE

Do not write 1h to the internal counter when the UC is in Freeze state. Doing so can cause the match to be missed and the counter to overflow.

63.5.3.15.2 MCB submodes and MODE field values

Table 411. MCB submodes and MODE field values

Submode or function	C*n*[MODE] (binary)
Internal clock source	101_0pp0b[1]

Table continues on the next page...

Table 411. MCB submodes and MODE field values (continued)

Submode or function	C*n*[MODE] (binary)
External clock source	101_0pp1b[1]
Up Count	101_000p[1]
Reserved	101_001p[1]
Up Count-Down Count	101_01pp[1]
Flag set only on match start	101_010p[1]
Flags also set at counter period boundary	101_011p[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

63.5.3.15.3 Up Count submode

In the Up Count submode:

- The internal counter (CNT*n*[C]) starts counting up (incrementing) from its current value.
- When the internal counter matches AS1 and a clock tick occurs (either prescaled clock or input pin event), the UC resets the internal counter to 1h.
- The UC sets the input-capture flag (S*n*[FLAG]) one system clock cycle after the match occurs.

You must write only values greater than 1h to AS1.

The boundary between counter period *n* and period *n*+1 occurs when the UC changes the internal counter from the AS1 value in period *n* to 1h in period *n*+1. AS1 defines the counter period.

The UC asserts the AS1 load signal (which has a duration of one system clock cycle) at the last system clock cycle of a counter period. This causes the UC to update AS1 with AS2 at the period boundary, at the same time that it resets the counter to 1h. Therefore, any value you write to AS2 during period *n* updates AS1 at the next period boundary and the UC uses it in period *n*+1. See Timing example: Up Count submode.

You can use Output Update Disable (OUDIS) to delay the update of AS1 for synchronization.

The UC sets the input-capture flag (S*n*[FLAG]) at the period boundary. See Timing example: Up Count submode flag assertion.

63.5.3.15.4 Timing example: Up Count submode

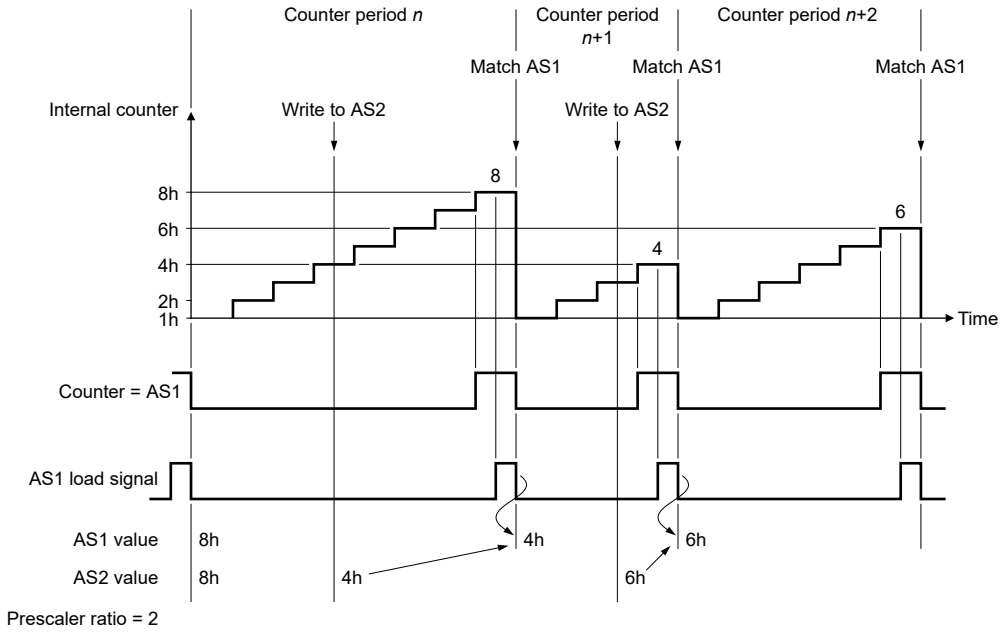

Figure 342. Timing example: Up Count submode

63.5.3.15.5 Timing example: Up Count submode flag assertion

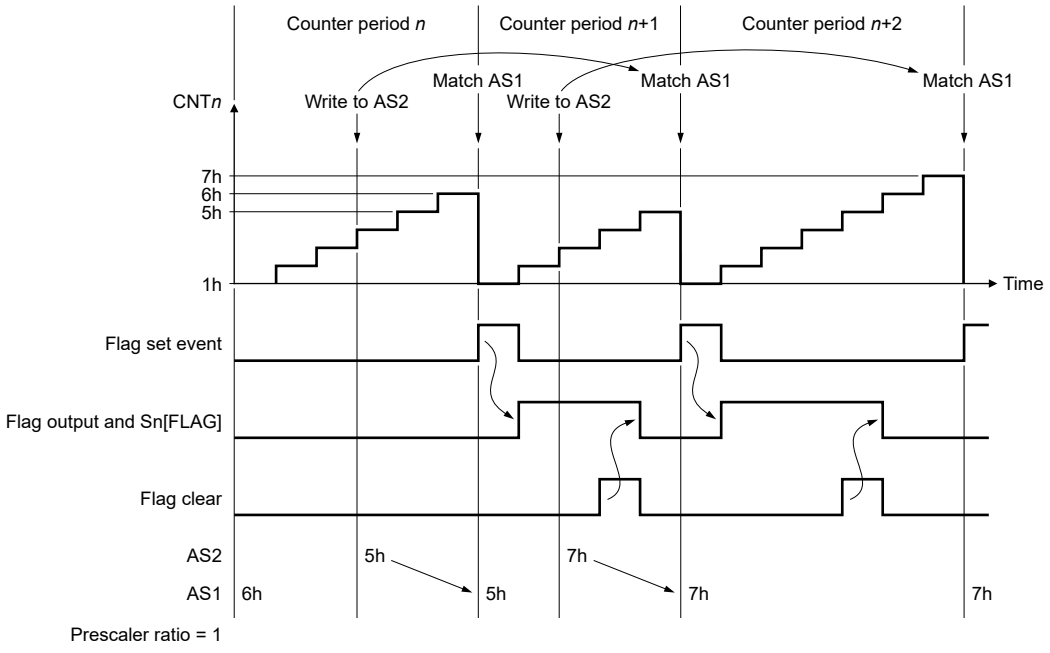

Figure 343. Timing example: Up Count submode flag assertion

63.5.3.15.6 Up Count-Down Count submode

In Up Count-Down Count submode:

- The counter period is: (2 x AS1) – 2. The counter changes direction at AS1 match and counts down (decrements) until it reaches 1h, then counts up (increments) again.
- BS1 generates a match to start the internal counter incrementing, and BS1 cannot be changed in this submode.

The UC updates AS1 at the counter period boundary. If you write AS2 (write A*n*[A]) during period *n*, the UC uses this new value in period *n*+1 for AS1 match. You can disable updates of AS1 (OUDIS[OU*n*]). See Timing example: Up Count-Down Count submode.

The UC sets the input-capture flag (S*n*[FLAG]) at AS1 match start, and may also do so at the period boundary. See Overview and Timing example: Up Count-Down Count submode flag assertion.

63.5.3.15.7 Timing example: Up Count-Down Count submode

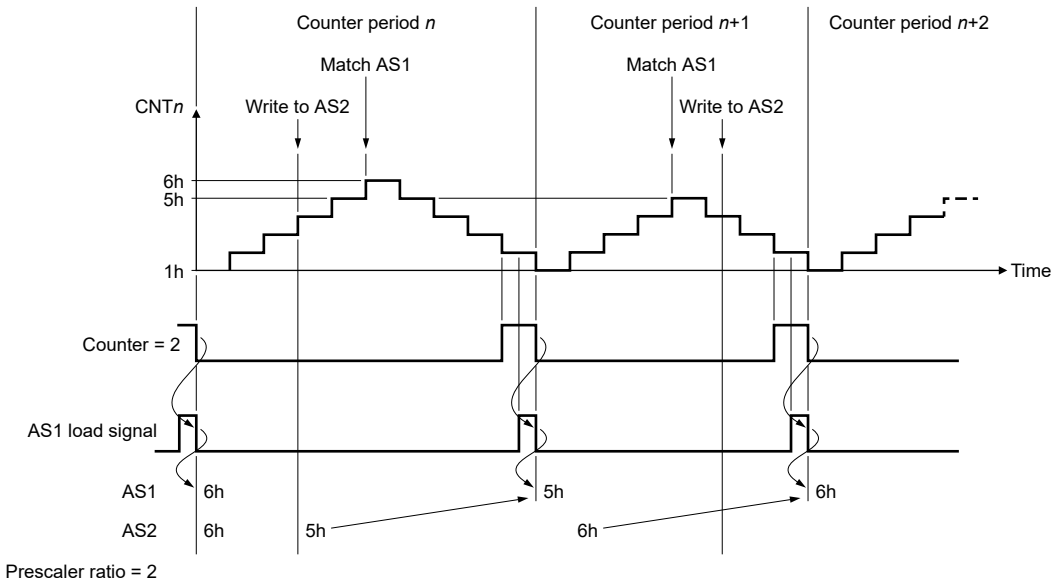

Figure 344. Timing example: Up Count-Down Count submode

63.5.3.15.8 Timing example: Up Count-Down Count submode flag assertion

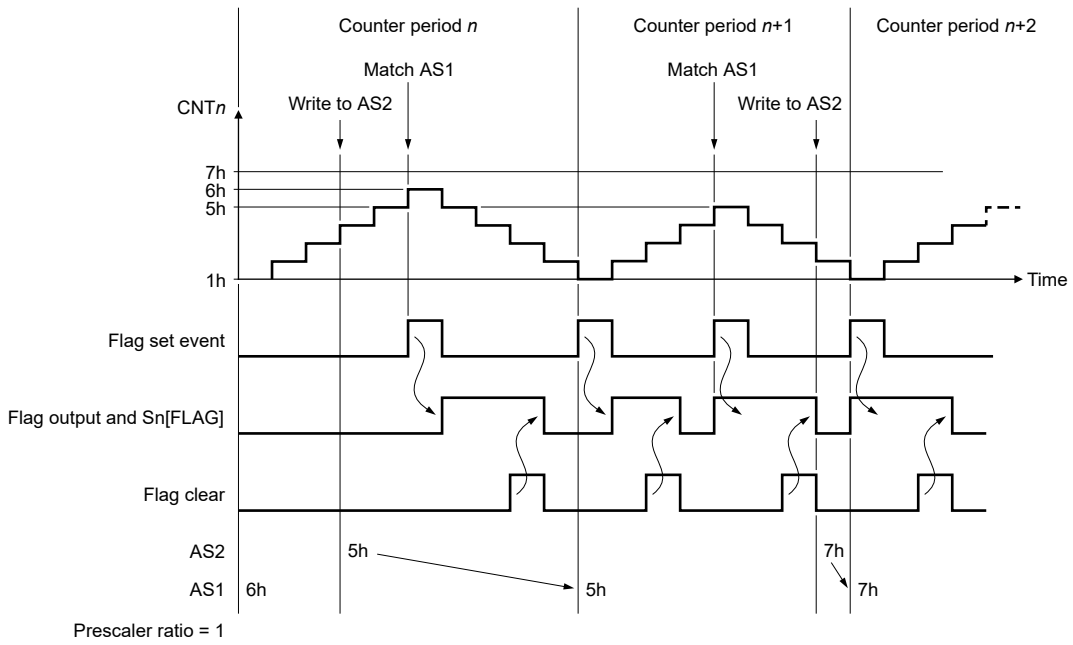

Figure 345. Timing example: Up Count-Down Count submode flag assertion

63.5.3.15.9 Up Count mode with delayed reload operation

When the internal counter matches AS1 in the Up Count submode or 1h in the Up Count-Down Count submode (see MCB submodes and MODE field values), the UC asserts the counter bus reload signal. You can read the counter bus reload signal in the following modes:

- Output PWM Buffered (OPWMB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

You can use the Reload Signal Output Delay Interval (C2[UCRELDEL_INT]) to cause the UC to assert the reload signal only after a specified number of match events (from 2 to 32).

See Timing example: Up Count mode with delayed reload.

63.5.3.15.10 Timing example: Up Count mode with delayed reload

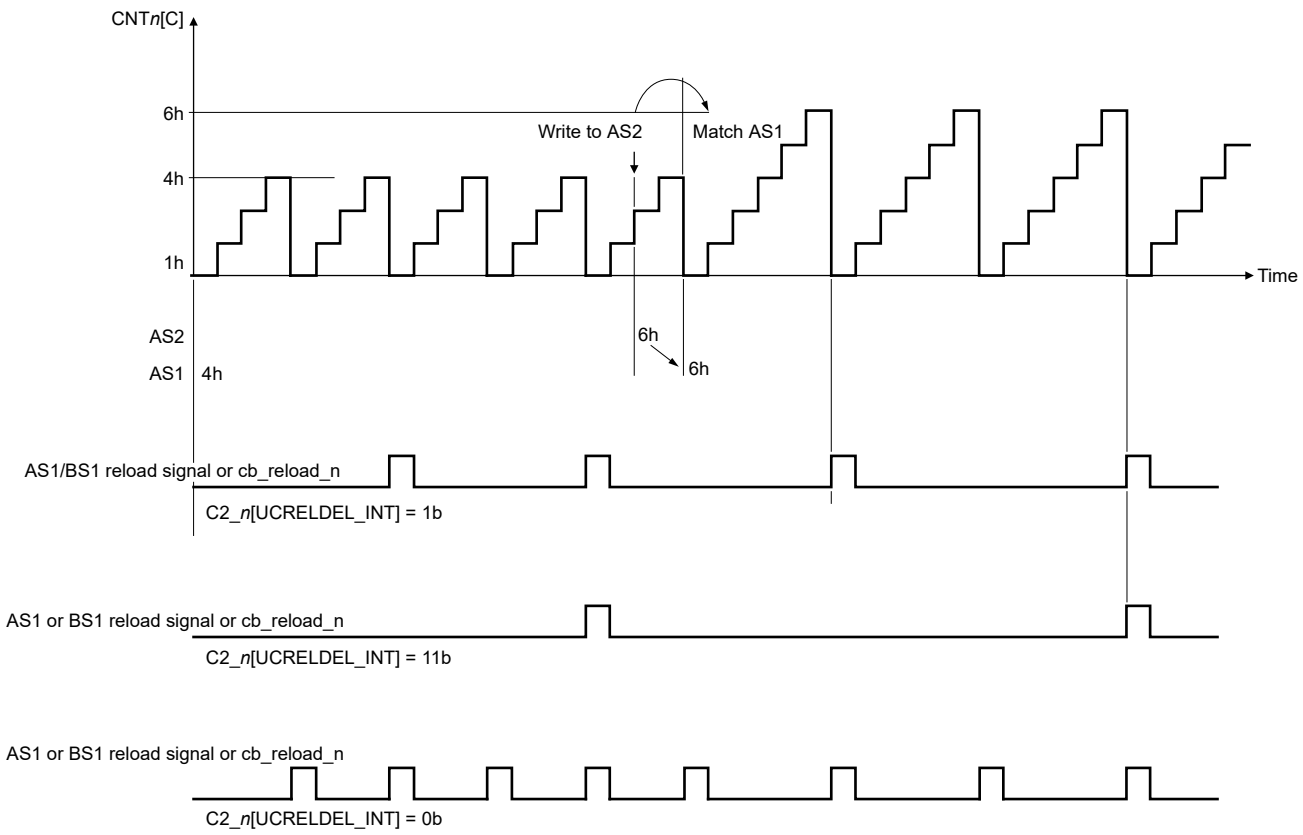

Figure 346. Timing example: Up Count mode with delayed reload

63.5.3.16 Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode

63.5.3.16.1 Overview

In this mode, the UC produces an output signal that has:

- A duty cycle determined by AS1.
- A period of BS1.

The double-buffered AS1 and BS1 registers produce smooth duty-cycle and period transitions when you change AS1 and BS1 during runtime.

See Table 418 for the values that you must write to C*n*[MODE] to enter this mode.

To provide smooth and consistent channel operation:

- AS1 and BS1 are both double-buffered to allow smooth signal generation when changing the register values.
- There is a delay from the AS1 match to the output pin transition (see AS1 and BS1 match timing).
- The internal counter ranges from 1h to BS1. When you write to BS1, you must write only values greater than 1h. Writing 0h or 1h leads to unpredictable results.

When a match on comparator A occurs, the UC drives C*n*[EDPOL] onto the output flip-flop. When a match on comparator B occurs, the UC drives the complement of C*n*[EDPOL] onto the output flip-flop. A BS1 match also causes the internal counter to transition to 1h, thus restarting the counter cycle.

The UC automatically selects the internal channel counter as the timebase when you select this mode. The mode supports duty cycles ranging from 0% to 100%.

63.5.3.16.2 OPWFMB submodes and MODE field values

Table 412. OPWFMB submodes and MODE field values

Match behavior	C*n*[MODE] (binary)
When BS1 matches the selected counter	101_1000
When AS1 or BS1 match the selected counter	101_1010

63.5.3.16.3 Avoid counter wrapping

When the UC enters OPWFMB mode, the output flip-flop acquires the value of C*n*[EDPOL]. If the UC transitions from GPIO to OPWFMB mode when the internal counter value is not within the range 1h–BS1, then the B match never occurs. Because the match never occurs, the internal counter wraps at the maximum counter value—FF_FFFFh for a 24-bit counter. When the counter wrap occurs, the counter returns to 1h and normal OPWFMB operation resumes. Therefore, to avoid this counter wrapping, ensure that the counter value is within the range 1h–BS1 before the UC enters OPWFMB mode.

63.5.3.16.4 AS1 and BS1 match timing

As illustrated in Timing example: AS1 and BS1 match, the output pin transition occurs when the AS1 or BS1 match signal deasserts, as indicated by the AS1 match negative-edge detection signal. If you write 4h to AS1, the output pin transitions 4 counter increments plus one system clock cycle after the counter period starts.

63.5.3.16.5 Timing example: AS1 and BS1 match

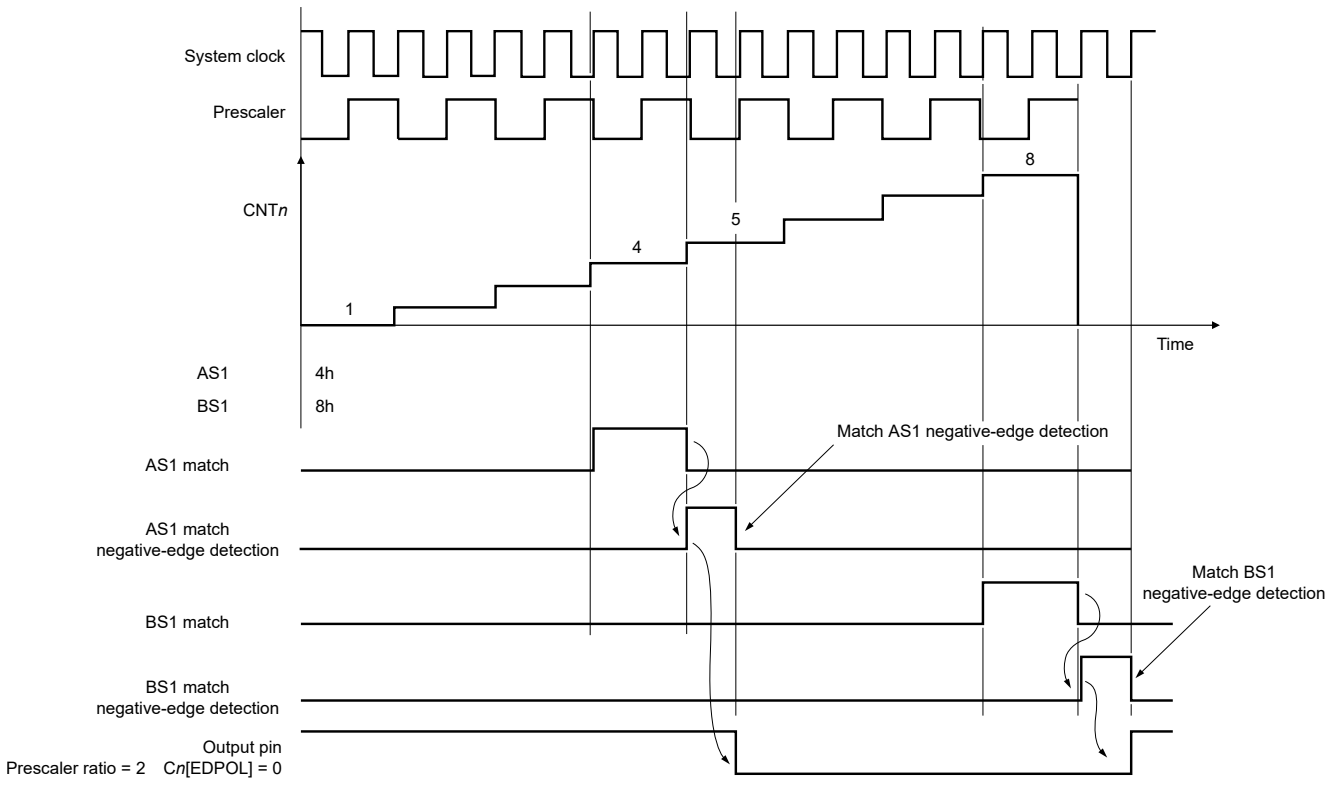

Figure 347. Timing example: AS1 and BS1 match

63.5.3.16.6 0% duty cycle

Timing example: AS1 = 0 illustrates the generated output signal when AS1 = 0, which results in a 0% duty cycle.

Because the internal counter never reaches zero in this situation, the UC infers a match as if AS1 = 1h. However, it is the positive edge of the match signal that triggers the output pin transition instead of the negative edge, which is what happens when AS1 = 1h. The AS1 positive-edge match signal from period *n*+1 occurs at the same time as the BS1 negative-edge match signal from period *n*. This timing allows the AS1 positive-edge match to mask the BS1 negative-edge match when they occur at the same time. As a result, no transition occurs on the output flip-flop and the UC generates a 0% duty cycle.

63.5.3.16.7 Timing example: AS1 = 0

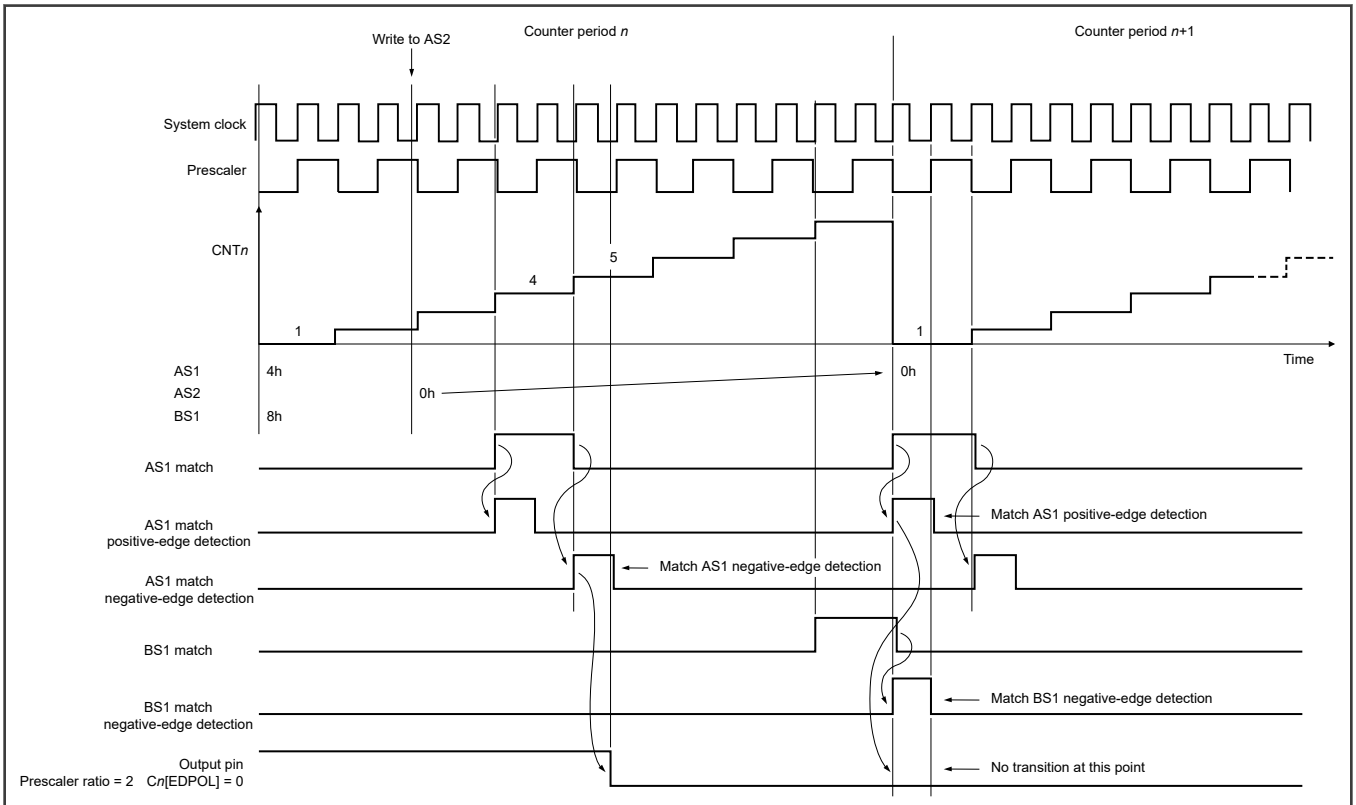

Figure 348. Timing example: AS1 = 0

63.5.3.16.8 Loading AS1 and BS1

As illustrated in Timing example: AS1 and BS1 update and FLAGs, AS1 and BS1 both use the same signal, generated at the last system clock cycle of a counter period. Therefore, eMIOS updates AS1 and BS1 with AS2 and BS2 values, respectively, at the same time that it changes the internal counter (CNT*n*[C]) to 1h. This event is the counter period boundary. The load signal pulse lasts for one system clock cycle. If you write AS2 and BS2 within counter period *n*, their values are available in AS1 and BS1, respectively, at the first clock cycle of counter period *n*+1. The UC then uses these new values for matches at counter period *n*+1. You can use Output Update Disable (OUDIS) to delay updating AS1 and BS1 for synchronization purposes.

63.5.3.16.9 Timing example: AS1 and BS1 update and FLAGs

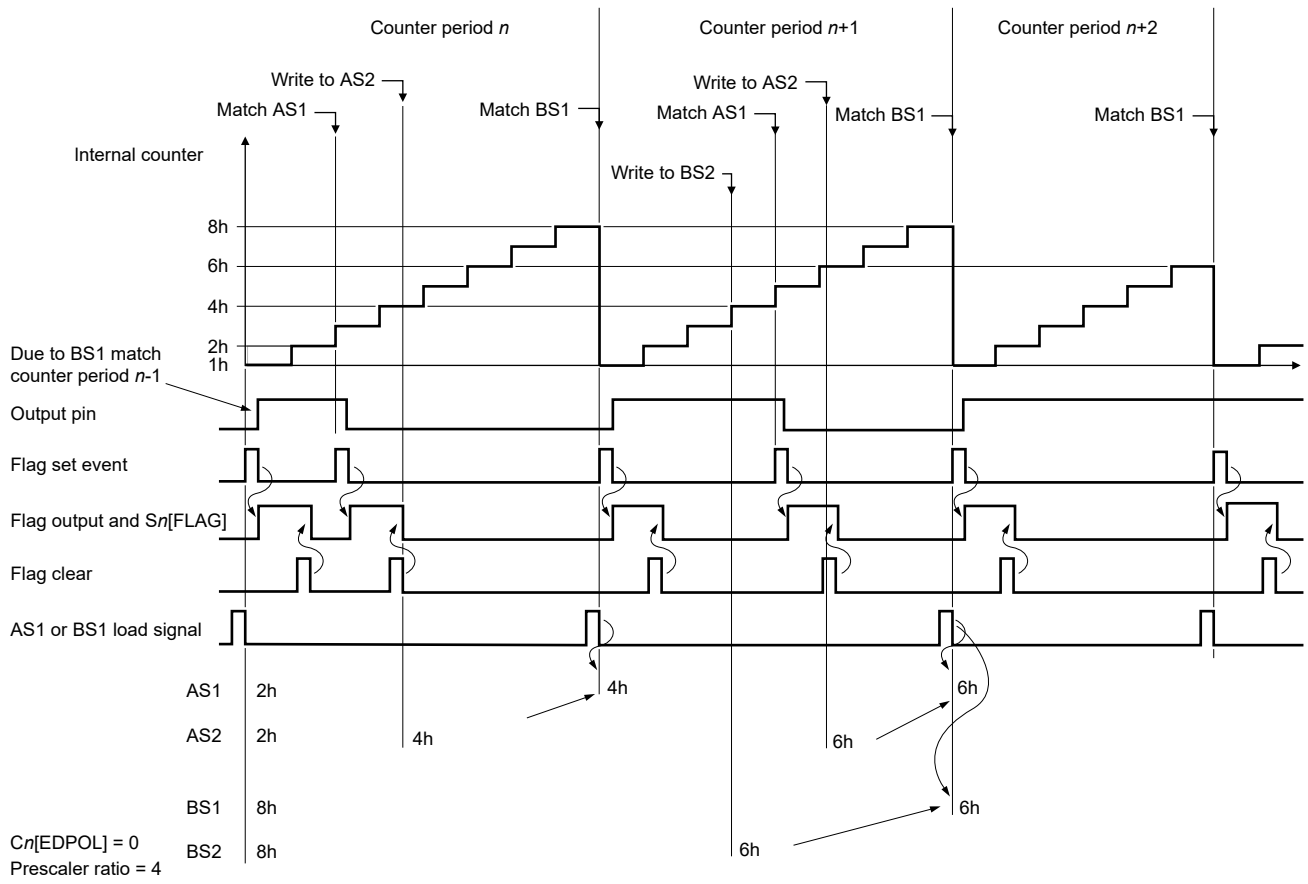

Figure 349. Timing example: AS1 and BS1 update and FLAGs

63.5.3.16.10 Flag generation

Timing example: AS1 and BS1 update and FLAGs assumes that both the channel and global prescalers are 1h (divide ratio of 2), causing the internal counter to transition every four system clock cycles. You can configure flags to be generated only on BS1 matches when bit 1 of C*n*[MODE] is 0, or on both AS1 and BS1 matches when that bit is 1. Because the BS1 flag occurs at the period boundary, you can use this flag to indicate that the AS2 or BS2 data written in period *n* has been loaded to AS1 or BS1, respectively, thereby generating matches in period *n*+1. Flag operation is synchronous, which means the flag sets one system clock cycle after the set-flag event.

63.5.3.16.11 Output disable

As illustrated in Timing example: active output disabled, the output-disable feature in OPWFMB mode forces the channel output flip-flop to the value of C*n*[EDPOL]. This functionality supports applications that use active-high signals and a high-to-low transition at an AS1 match. In this case, you must write 0 to C*n*[EDPOL]. You also must configure the internal counter to transition on every system clock cycle (write 0 to both GCP and CP).

The output-disable feature operates synchronously, meaning that the assertion of the Output Disable input signal causes the channel output flip-flop to transition to C*n*[EDPOL] at the next system clock cycle. If the Output Disable input pin deasserts, the output-signal transition occurs at the next AS1 or BS1 match.

Timing example: active output disabled assumes that the Output Disable input is enabled (using C*n*[ODIS]) and selected (using C*n*[ODISSL]). See UC Control n (C0 - C23) for a detailed description of the ODIS and ODISSL fields that enable and select the Output Disable inputs, respectively.

63.5.3.16.12 Timing example: active output disabled

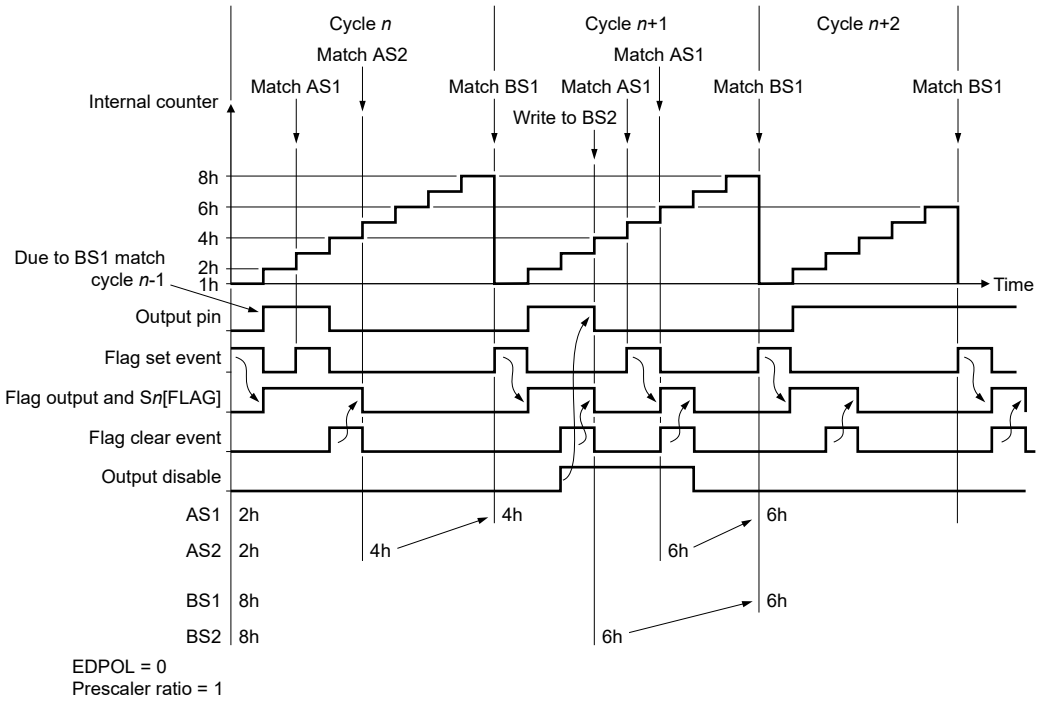

Figure 350. Timing example: active output disabled

63.5.3.16.13 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. Similarly to a BS1 match, Force Match B changes the internal counter to 1h. The force-match operations do not set the input-capture flag (S*n*[FLAG]).

63.5.3.16.14 100% and 0% duty cycles

Timing example: from 100% to 0% duty cycle illustrates the generation of 100% and 0% duty-cycle signals. Initially, AS1 = 8h and BS1 = 8h. In this case, a BS1 match has precedence over an AS1 match—therefore, the output flip-flop acquires the complement of C*n*[EDPOL]. This configuration corresponds to a 100% duty-cycle signal. The same output signal can be generated for any AS1 value greater than or equal to BS1.

If AS1 is 0, the UC generates a 0% duty-cycle signal. In this case, the BS1 = 8h match from period 8 occurs at the same time as the AS1 = 0h match from period 9. See Timing example: AS1 = 0 for AS1 and BS1 match generation. In this case, an AS1 match has precedence over a BS1 match, and the output signal transitions to C*n*[EDPOL].

63.5.3.16.15 Timing example: from 100% to 0% duty cycle

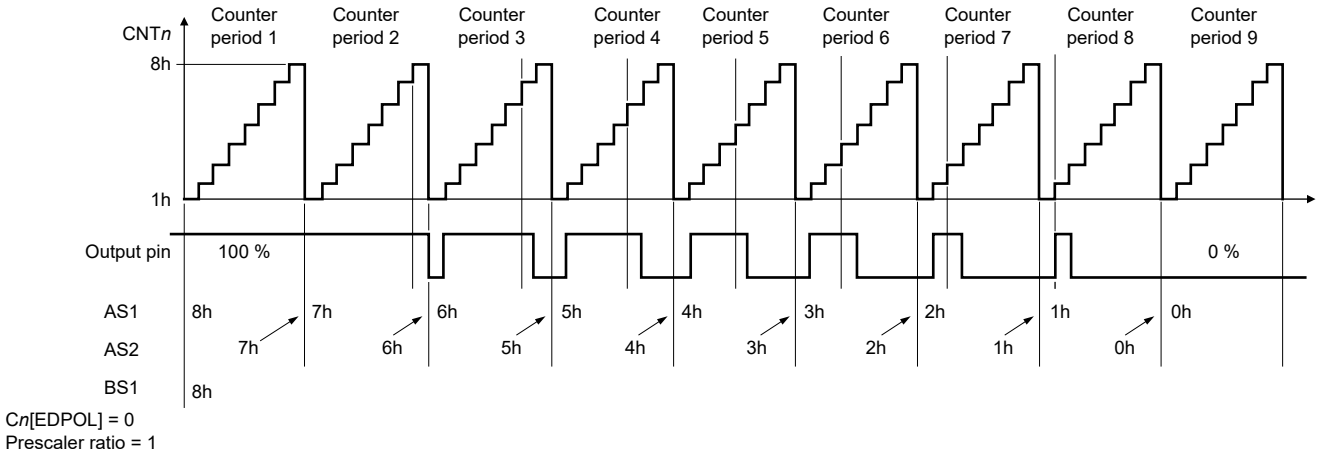

Figure 351. Timing example: from 100% to 0% duty cycle

63.5.3.17 Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

63.5.3.17.1 Overview

In this mode, the UC generates a center-aligned PWM pulse with dead time insertion in the leading or trailing edge. See OPWMCB functions and MODE field values. AS1 and BS1 are double-buffered to allow smooth output signal generation when you change the AS2 or BS2 values.

When the UC enters OPWMCB mode from GPIO mode:

- The UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Select the timebase using Bus Select (C*n*[BSL]). The timebase you select must be running in Up Count-Down Count mode. See Timing example: Up Count submode flag assertion. You must start the MCB timebase after the UC enters OPWMCB mode to avoid missing a match on the first duty cycle.
- Store the ideal duty cycle for the PWM signal in AS1 (write to A*n*[A]), which the UC compares with the selected timebase.
- Store the dead time value in BS1 (write to B*n*[B]), which the UC compares with the internal counter (CNT*n*[C]).

The internal counter may use the internal prescaler ratio, while the selected timebase may use a different prescaler ratio. The UC always resets the internal counter to 1h when an AS1 match occurs.

As in OPWMB and OPWFMB modes, the UC generates the match signal which compares the selected timebase with AS1 or BS1. When the UC deasserts the channel's combinational comparator output signal, it uses the match signal to assert or negate the channel's output flip-flop. See Timing example: AS1 and BS1 match for an illustration of the delay from match to output flip-flop transition in OPWFMB mode. The operation of OPWMCB mode is similar to OPWFMB mode with respect to match behavior and output pin transition.

See Entering OPWMCB mode.

63.5.3.17.2 OPWMCB functions and MODE field values

Table 413. OPWMCB functions and mode field values

Function	C*n*[MODE] (binary)
Insert trailing edge dead time with duty cycle determined by BS1 + AS1	101_11p0[1]

Table continues on the next page...

Table 413. OPWMCB functions and mode field values (continued)

Function	C*n*[MODE] (binary)
Insert leading edge dead time with duty cycle determined by BS1 – AS1	101_11p1[1]
Assert the input capture flag (Sn[FLAG]) on the trailing edge of the output PWM signal	101_110p[1]
Assert the input capture flag (Sn[FLAG]) on both edges of the output PWM signal	101_111p[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

63.5.3.17.3 Entering OPWMCB mode

To enter OPWMCB mode (this procedure assumes the channel is initially in GPIO mode):

1. Disable the GCP (write 0 to MCR[GPREN]).
2. For the timebase (MCB) channel:
   a. Disable the CP (write 0 to C*n*[UCPREN]).
   b. Initialize the internal counter (write 1h to CNT*n*[C]).
   c. Initialize the A data (write appropriate value to A*n*[A]).
   d. Configure the UC for MCB Up Count-Down Count mode (write 101_01*xy*b to C*n*[MODE], where *x* = 0 for flag set on match start or *x* = 1 for flag set at period boundary, and *y* = 0 for internal clock source or *y* = 1 for external clock source).
   e. Select the CP ratio (C*n*[UCPRE]).
   f. Enable the CP (write 1 to C*n*[UCPREN]).
3. For the OPWMCB channel:
   a. Disable the CP (write 0 to C*n*[UCPREN]).
   b. Initialize the A data (write appropriate value to A*n*[A]).
   c. Initialize the B data (write appropriate value to B*n*[B]).
   d. Select the timebase input (C*n*[BSL]).
   e. Configure the UC for MCB Up Count-Down Count mode (write 101_01*xy*b to C*n*[MODE], where *x* = 0 for flag set on match start or *x* = 1 for flag set at period boundary, and *y* = 0 for internal clock source or *y* = 1 for external clock source).
   f. Select the CP ratio (C*n*[UCPRE]).
   g. Enable the CP (write 1 to C*n*[UCPREN]).
4. Enable the GPC (write 1 to MCR[GPREN]).

63.5.3.17.4 Timing example: AS1 and BS1 load

When the selected counter bus transitions from 2h to 1h:

- The UC loads AS1 and BS1 as shown in the following figure.
- This event defines the counter period boundary.

The UC loads the values you write to AS2 or BS2 within period *n* into AS1 or BS1, respectively, and uses them to generate matches in period *n*+1.

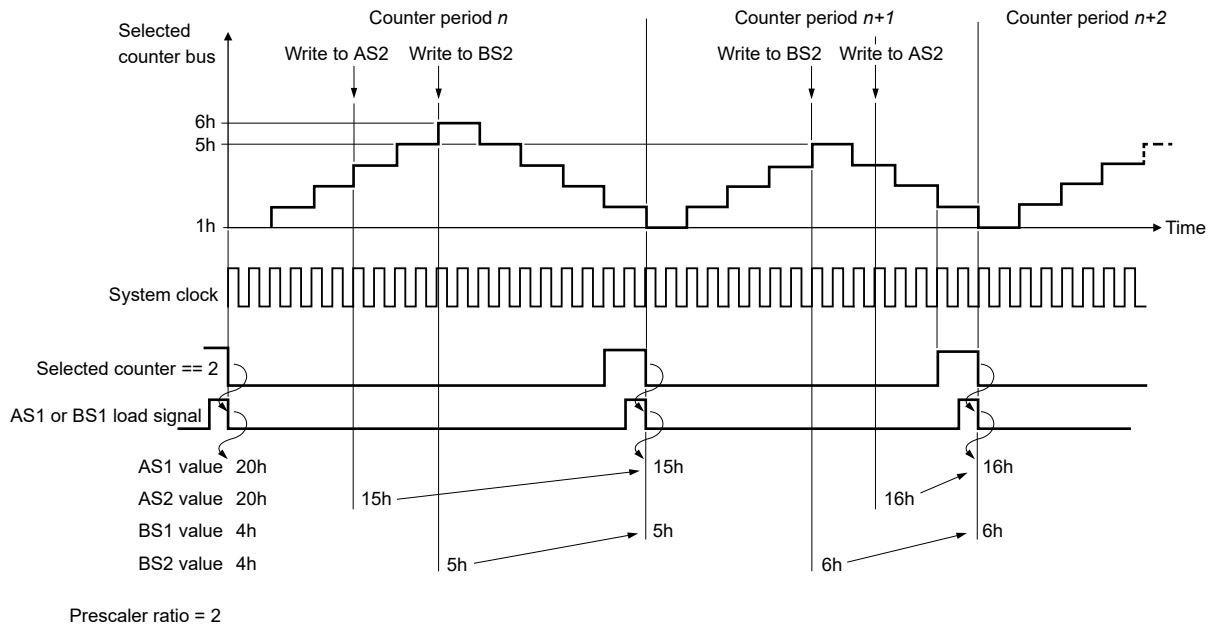

Figure 352. Timing example: AS1 and BS1 load

63.5.3.17.5 Operation sequence with leading edge dead time insertion

When operating with leading edge dead time insertion:

1. When the first AS1 match occurs, the UC writes 1h to the internal counter.
2. When a match between BS1 and the internal timebase occurs, the UC drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
3. When the next match between AS1 and the selected timebase occurs, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

The UC repeats the above sequence continuously.

You must not allow the internal counter to reach 0h as the result of a rollover. To avoid this, you must not write a value greater than

2 x ((external Count Up limit) – A*n*[A])

into B*n*[B].

See Timing example: leading dead time insertion.

63.5.3.17.6 Timing example: leading dead time insertion

This example illustrates two cycles of a center-aligned PWM signal. AS1 and BS1 values change within the same period, which allows you to change the duty cycle and dead time values at the same time.

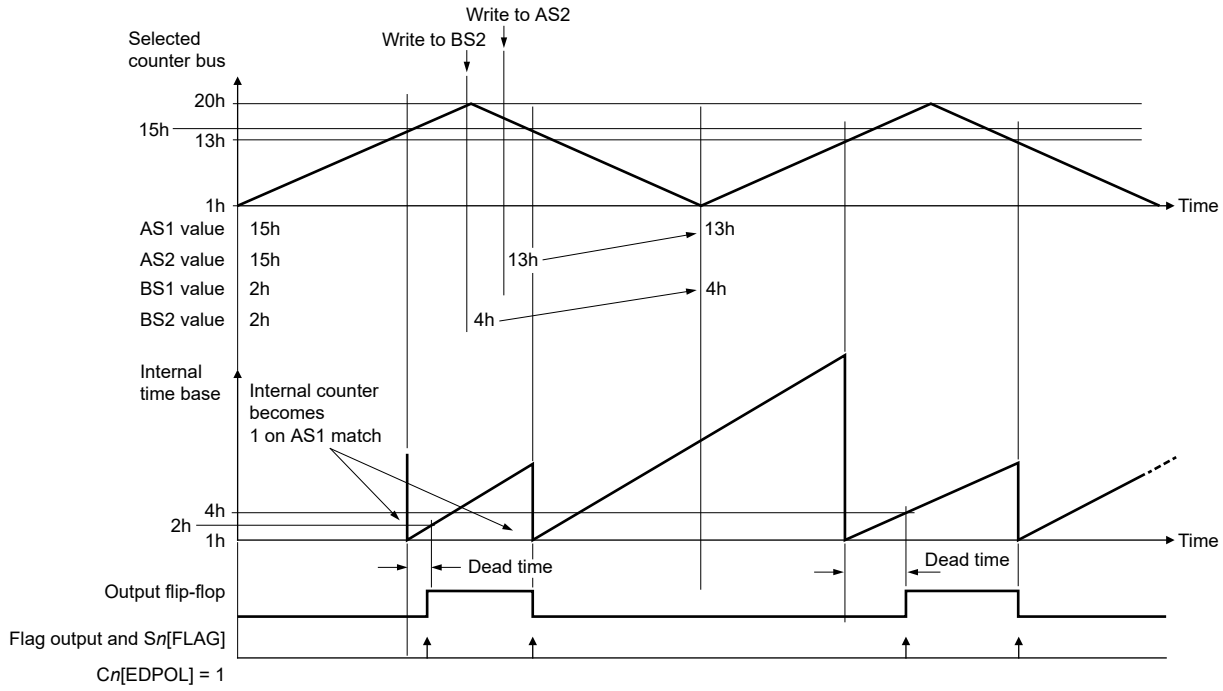

Figure 353. Timing example: leading dead time insertion

63.5.3.17.7 Operation sequence with trailing edge dead time insertion

When operating with trailing edge dead time insertion:

1. When the first match between AS1 and the selected timebase occurs, the UC:
   a. Drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
   b. Writes the internal counter (CNT*n*[C]) to 1h.
2. When the second match between AS1 and the selected timebase occurs, the UC:
   a. Writes the internal counter to 1h.
   b. Enables BS1 matches.
3. When a match between BS1 and the selected timebase occurs, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

The UC repeats this sequence continuously.

63.5.3.17.8 Timing example: trailing dead time insertion

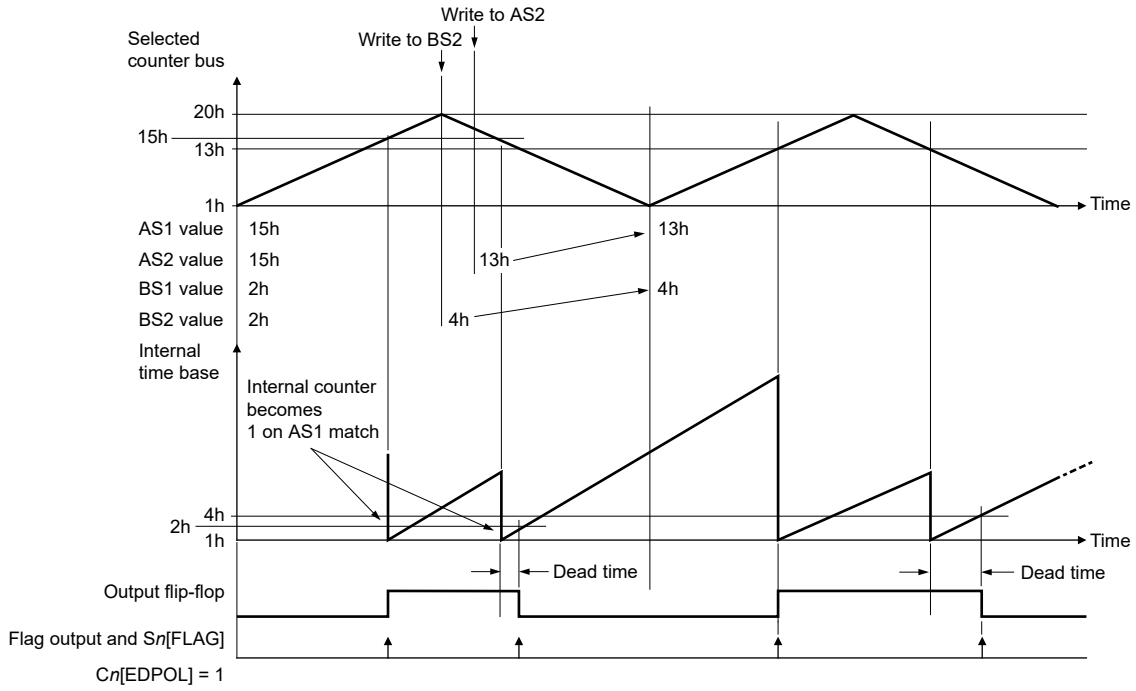

Figure 354. Timing example: trailing dead time insertion

63.5.3.17.9 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. If subsequent matches occur on comparators A and B, the UC continues to generate PWM pulses regardless of the input capture flag (S*n*[FLAG]). The force-match operations do not set the input-capture flag (S*n*[FLAG]).

When you select leading edge dead time insertion:

- Force Match A drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Force Match B drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

When you select trailing edge dead time insertion:

- Force Match A drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Force Match B drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

Force Match operation does not write 1h to the internal timebase.

Force Match operation does not set the input-capture flag.

When you assert Force Match A and Force Match B at the same time, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop. This is the equivalent of saying that Force Match A has precedence over Force Match B when you select leading edge dead time insertion, and Force Match B has precedence over Force Match A when you select trailing edge dead time insertion.

Force Match A and Force Match B have the same output transition behavior in both Freeze state and unfrozen state.

63.5.3.17.10 Duty cycle

You generate a duty cycle from 0% to 100% by writing appropriate values to AS1 and BS1 relative to the period of the external timebase.

To generate a 100% duty cycle waveform:

- Select trailing edge dead time insertion (see OPWMCB functions and MODE field values).
- Write 1h to Edge Polarity (C*n*[EDPOL]).
- The BS1 match must occur on or after the counter period boundary (external counter = 1).

You can also generate a 100% duty cycle waveform by writing 1h to AS1. However, if you do this before the UC enters OPWMCB mode, a 100% duty cycle may not occur in the first PWM period depending upon the pin state at mode entry.

To generate a 0% duty cycle waveform:

- AS1 must be greater than the maximum value of the selected counter period.
- The pin must start the current period with the complement value of Edge Polarity (C*n*[EDPOL]). If starting at 100% duty cycle, you can change Edge Polarity (C*n*[EDPOL]) to its complement by forcing the pin (see Force match).

You must write only non-zero values to AS1. If you write the maximum value of the external counter given by

(external counter period)/2

to AS1, the UC constantly drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

UC logic prevents matches from one period propagating to the next period. In trailing edge dead time insertion, the UC masks out BS1 matches that occur late in period *n*, so matches in period *n*+1 are unaffected and the output flip-flop does not transition.

63.5.3.17.11 Timing example: duty cycle

To generate a 100% duty cycle output waveform, write 4h to AS1 and 3h to BS1, as illustrated in this diagram. In this case, the trailing edge is at the boundary of counter period *n*+1, which actually belongs to period *n*+2 and therefore does not cause the output flip-flip to transition.

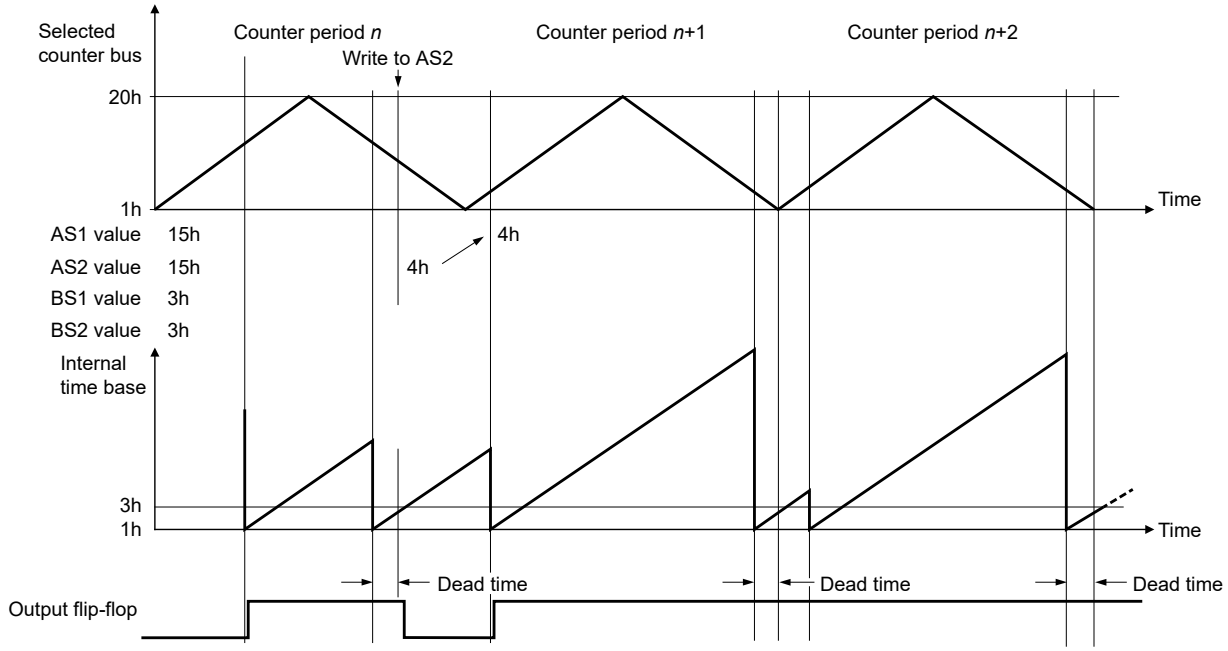

Figure 355. Timing example: duty cycle

63.5.3.17.12 Output disable

You can use Output Update Disable (write 0 to OUDIS[OU*n*]) to disable AS1 and BS1 updates. This allows you to update AS1 and BS1 in the same counter period and synchronize the loading of these registers with the loading of AS1 or BS1 in other channels.

Asserting Output Update Disable drives the complement of Edge Polarity (C*n*[EDPOL]) on output flip-flop. The internal channel matches continue to occur, and therefore the UC continues to set flags.

When you deassert Output Update Disable, the output flip-flop is again controlled by AS1 and BS1 matches. The UC transitions the output flip-flop only on system clock edges.

63.5.3.18 Output PWM Buffered (OPWMB) mode

63.5.3.18.1 Overview

In this mode, the UC produces PWM pulses with programmable leading and trailing edge placement. You must select an external counter driven in MCB Up mode from one of the counter buses. AS1 and BS1 define the first and second edges, respectively. C*n*[EDPOL] defines the output signal polarity. If C*n*[EDPOL] = 0, a negative edge occurs when AS1 matches the selected counter bus and a positive edge occurs when BS1 matches the selected counter bus.

See OPWMB submodes and MODE field values for the values that you must write to C*n*[MODE] to enter this mode.

AS1 and BS1 are double-buffered and updated from AS2 and BS2, respectively, at the cycle boundary. The load operation is similar to the one that occurs in OPWFMB mode. See Timing example: AS1 and BS1 update and FLAGs for more information about AS1 and BS1 updates.

When the UC enters OPWMB mode, the UC drives C*n*[EDPOL] on the output flip-flop.

These rules apply to OPWMB mode:

- If the AS1 and BS1 matches occur at the same time within the same counter period, the BS1 match has precedence over the AS1 match.
- An AS1 = 0 match in period *n* has precedence over a BS1 match in period *n*-1.
- The UC masks out AS1 matches if they occur after a BS1 match within the same period.
- The UC loads any value that you write to AS2 or BS2 in period *n* into AS1 and BS1 at the following period boundary (assuming that the corresponding OU*n* field of Output Update Disable (OUDIS) is 0). Therefore, the UC uses the new values for AS1 and BS1 matches in period *n*+1.

Timing example: 100% to 0% duty cycle illustrates a waveform changing from 100% to 0% duty cycle. In this example, BS1 is programmed to the same value as the period of the external selected timebase. If you write a value smaller than 8h to BS1, you cannot achieve a 0% duty cycle by only changing AS1. Because BS1 matches have precedence over AS1 matches, the flag output transitions to the complement of C*n*[EDPOL] at a BS1 match. For another example, if you write 9h to BS1, a BS1 match does not occur, and the UC generates a 0% duty-cycle signal.

63.5.3.18.2 OPWMB submodes and MODE field values

Table 414. OPWMB submodes and MODE field values

When FLAG generation occurs	C*n*[MODE] (binary)
At a BS1 match	110_0000
At an AS1 or BS1 match	110_0010

63.5.3.18.3 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. If subsequent matches occur on comparators A and B, the UC continues to generate PWM pulses regardless of the input capture flag (S*n*[FLAG]). The force-match operations do not set the input-capture flag (S*n*[FLAG]).

63.5.3.18.4 Matches and flag operation

Timing example: matches and flags illustrates the operation of OPWMB mode with an emphasis on AS1 and BS1 matches and the transition of the channel output pin. The output pin transitions are based on the negative edges of the AS1 and BS1 match signals. AS1 becomes zero in period *n*+1. In this case, the UC uses the match positive edge instead of the negative edge to transition the output flip-flop.

63.5.3.18.5 Timing example: matches and flags

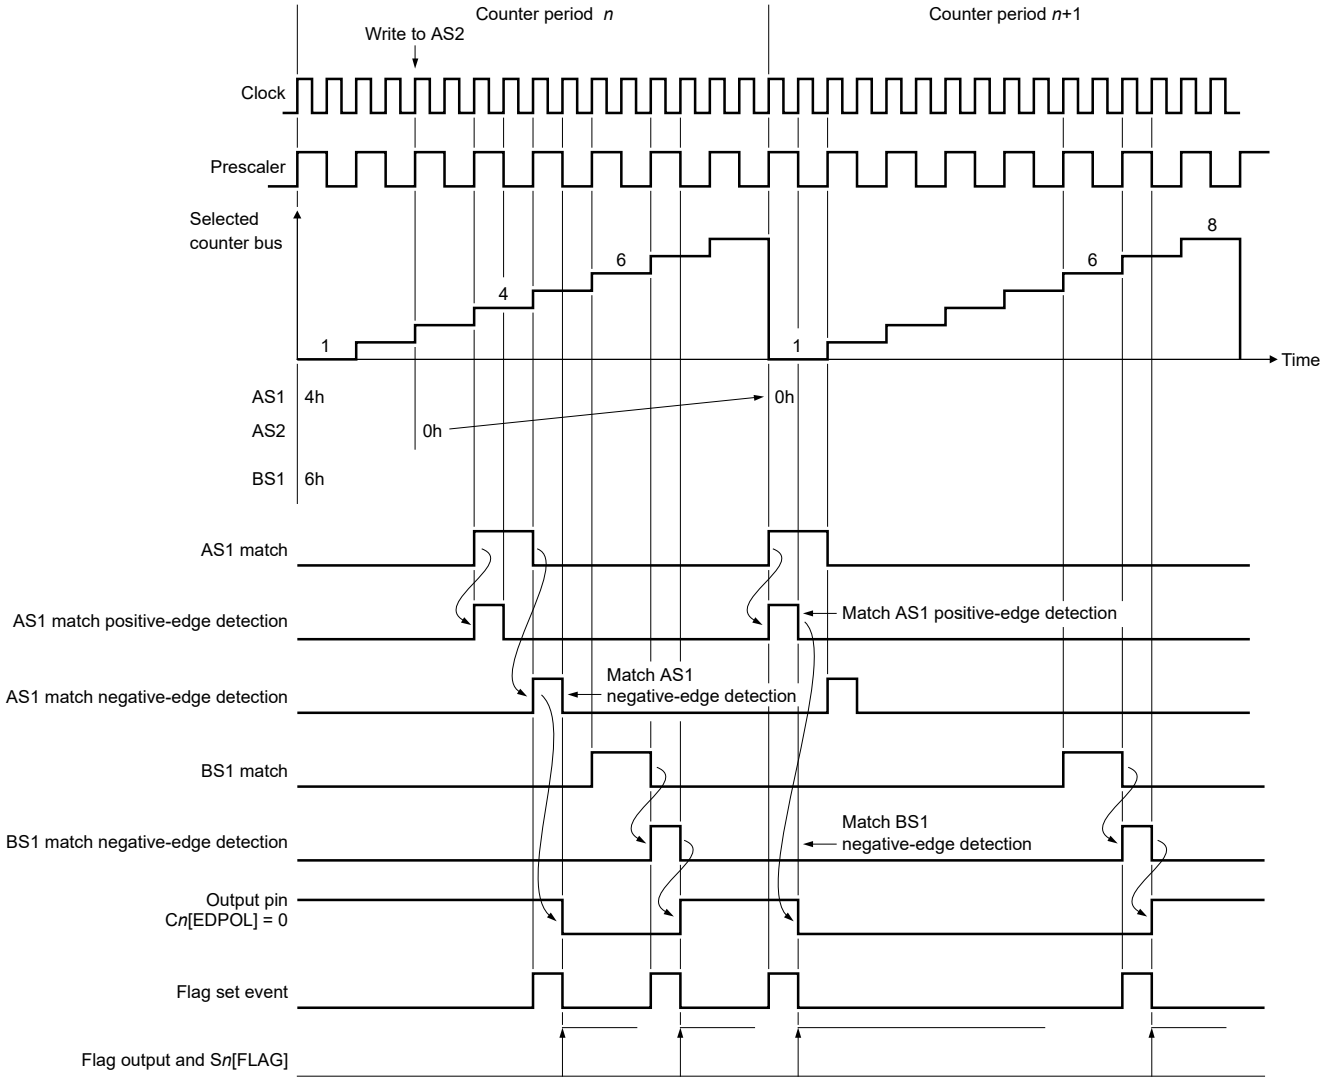

Figure 356. Timing example: matches and flags

63.5.3.18.6 0% duty cycle

Timing example: 0% duty cycle illustrates the channel operation for a 0% duty cycle. The AS1 match positive-edge signal occurs at the same time as the BS1 = 8h negative-edge signal. In this case, the AS1 match has precedence over the BS1 match, causing the output pin to remain at the value of C*n*[EDPOL] and generating a 0% duty-cycle signal.

63.5.3.18.7 Timing example: 0% duty cycle

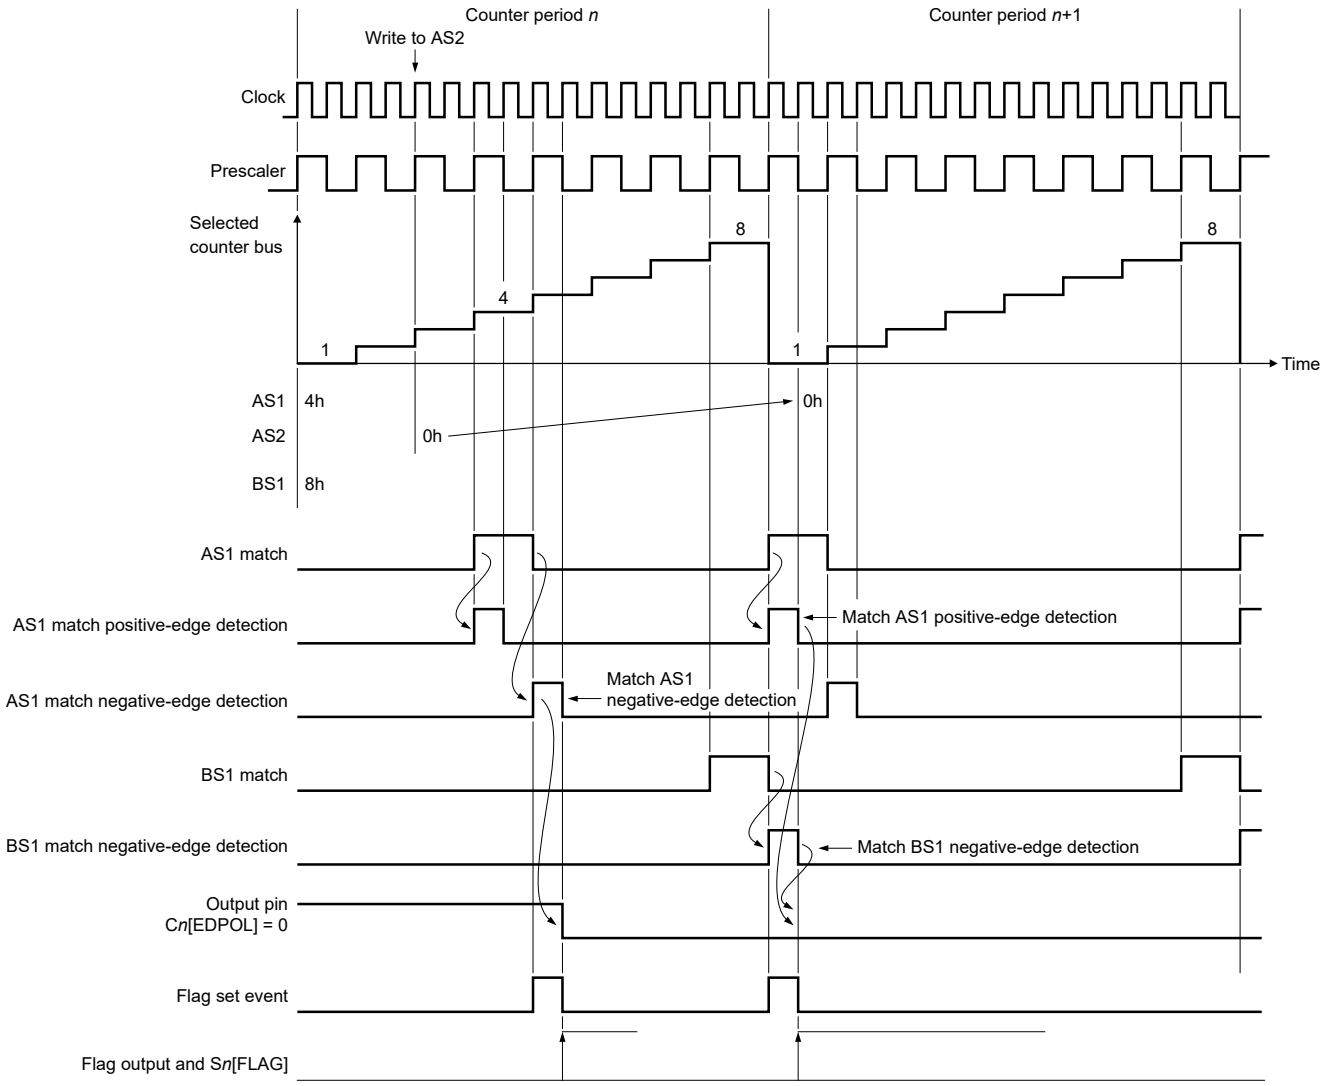

Figure 357. Timing example: 0% duty cycle

63.5.3.18.8 Active output disabled

Timing example: active output disabled illustrates the operation of the OPWMB mode with an emphasis on the assertion of the output-disable signal. The output disable forces a transition in the output pin to the value of C*n*[EDPOL]. The deassertion of the output-disable signal allows the output pin to transition at the following AS1 or BS1 match. The output disable does not modify the behavior of S*n*[FLAG]. A delay of one system clock cycle exists between the assertion of the output-disable signal and the transition of the output pin to C*n*[EDPOL].

63.5.3.18.9 Timing example: active output disabled

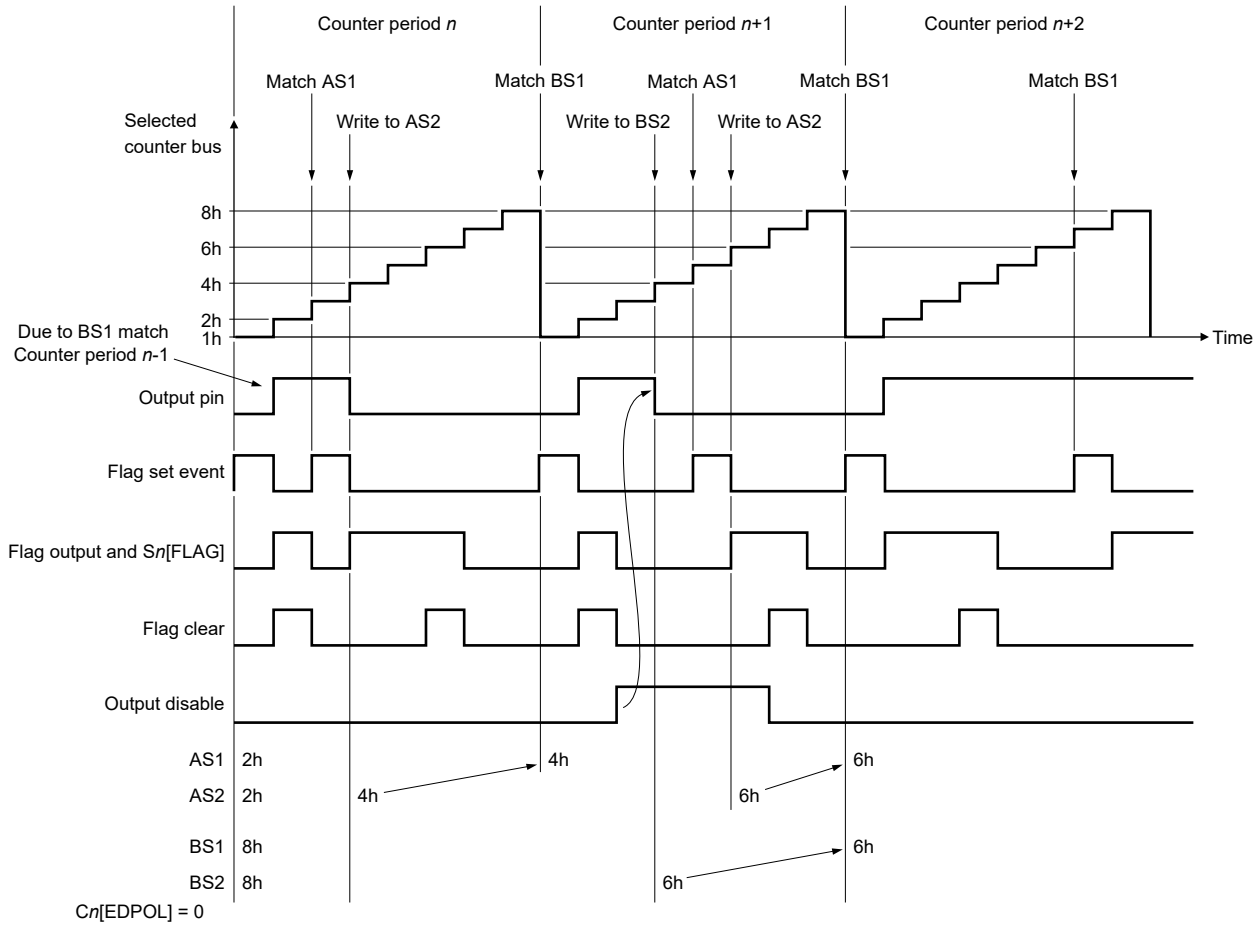

Figure 358. Timing example: active output disabled

63.5.3.18.10 Changing from 100% to 0% duty cycle

Timing example: 100% to 0% duty cycle illustrates a waveform changing from 100% to 0% duty cycle. In this example, BS1 has the same value as the period of the external selected timebase. If you write a value smaller than 8h to BS1, you cannot achieve a 0% duty cycle by only changing AS1. Because BS1 matches have precedence over AS1 matches, the output pin transitions to the complement of C*n*[EDPOL] at a BS1 match. For another example, if you write 9h to BS1, a BS1 match does not occur, and the UC generates a 0% duty-cycle signal.

63.5.3.18.11 Timing example: 100% to 0% duty cycle

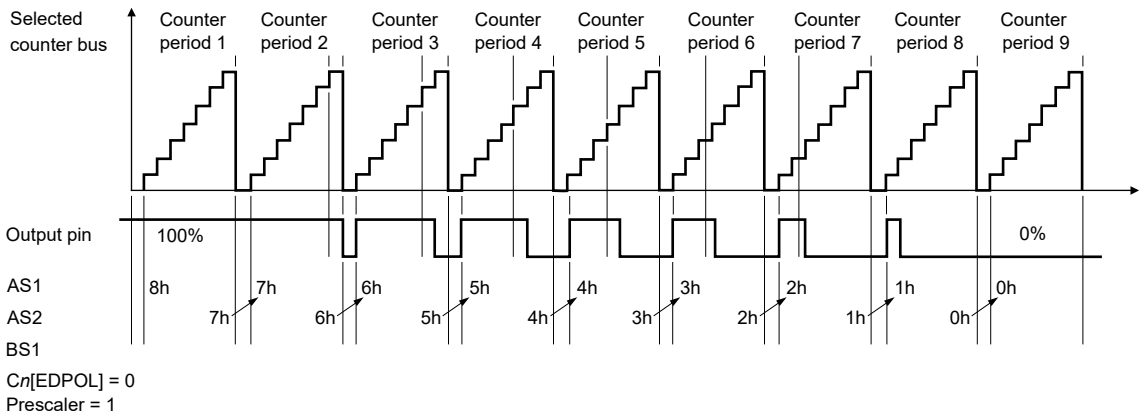

Figure 359. Timing example: 100% to 0% duty cycle

63.5.3.19 Output PWM with Trigger (OPWMT) mode

63.5.3.19.1 Overview

In this mode, the UC generates PWM pulses where the period does not change while the UC outputs the signal, but the duty cycle changes. When the duty cycle changes, it must not create glitches. The mode supports multiple UCs executing in the same mode and sharing a common timebase. Each UC can have a fixed PWM leading-edge position with respect to the other UCs. It can also generate a trigger signal at any point in the period. eMIOS can output this trigger signal to initiate activity in other parts of the chip—for example, to start ADC conversions.

You must select an external counter, driven in either MC Up or MCB Up mode (see Modulus Counter Buffered (MCB) mode), from one of the counter buses.

AS1 in OPWMT mode, AS2 in OPWMT mode, and BS1 and BS2 in OPWMT mode describe the configuration and behavior of the individual shadow registers in this mode.

To account for the shift in the AS1-defined leading edge of the waveform, the BS1-defined trailing edge may roll over into the next period. This means that a match against BS1 does not have to be qualified by a match in AS1. This also means that if you incorrectly write a value less than AS1 to BS1, the output persists over a period boundary until the UC encounters the BS1 value.

This mode provides a buffered update of the trailing edge by updating BS1 with BS2 contents only at a match of AS1.

The positive edges of the AS1, BS1, and AS2 match signals drive the output pin and flag transitions. See Timing example: matches and flags for details on positive-edge matches.

The UC sets the input capture flag (S*n*[FLAG]) only at an AS2 match. An AS1, BS1, or BS2 match has no effect on the flag.

When the UC enters OPWMT mode, it drives the complement of C*n*[EDPOL] on the output flip-flop.

Timing example: OPWMT illustrates the UC running in OPWMT mode with trigger-event generation and duty-cycle update after the next-period update.

63.5.3.19.2 Timing example: OPWMT

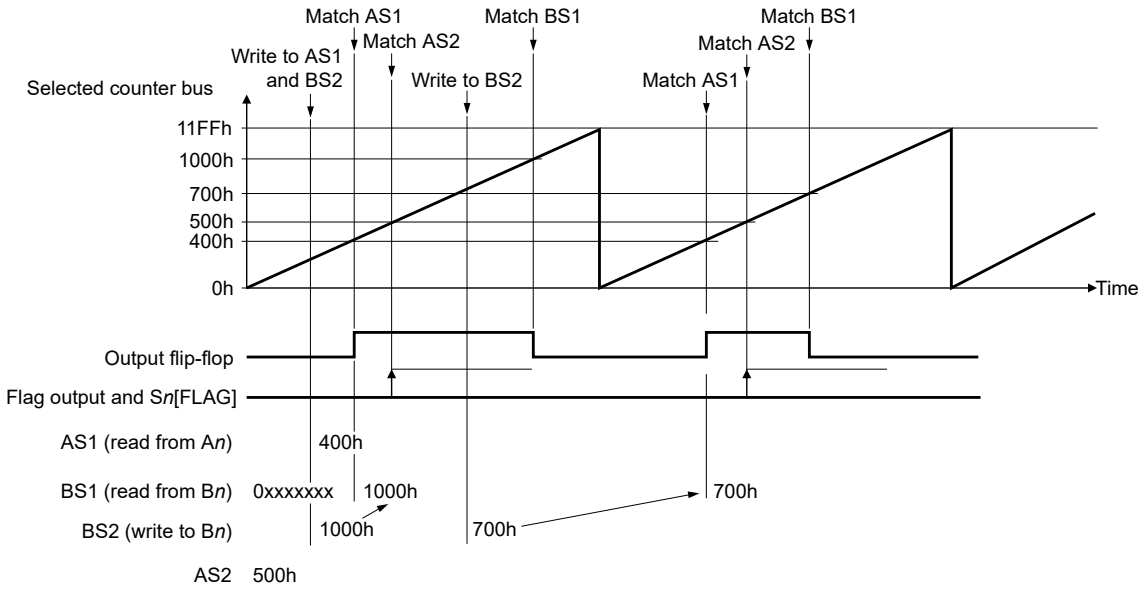

Figure 360. Timing example: OPWMT

63.5.3.19.3 AS1 in OPWMT mode

AS1 defines the leading edge of the PWM pulse output, and therefore the beginning of the PWM period. Using this fact, you can ensure that, when using a shared timebase, the leading edges of multiple UCs in OPWMT mode occur at specific times with respect to the other UCs. You can also introduce a fixed offset for each UC, which is particularly useful in the generation of lighting control signals. For this application, to reduce or eliminate noise generation, you can shift the PWM pulse of each UC with respect to the selected timebase by adjusting the AS1 value for each channel. The value you write to AS1 must be within the range of the selected timebase. Shadow registers (AS1, AS2, BS1, and BS2) loaded with 0h do not produce matches if the channel driving the timebase is in MCB mode.

AS1 is not buffered, because the shift of a PWM channel must not change while the UC generates the PWM signal. If you modify AS1, it updates immediately and one PWM pulse could be lost.

The UC compares AS1 to the selected timebase. When a match on AS1 occurs, the UC drives C*n*[EDPOL] on the output flip-flop. When a match occurs on comparator B, the UC drives the complement of C*n*[EDPOL] on the output flip-flop.

63.5.3.19.4 AS2 in OPWMT mode

AS2 defines the generation of a trigger event within the PWM period. The value you write to AS2 must be within the range of the selected timebase—otherwise the UC does not generate a trigger. A match on the comparator asserts the input-capture flag, but the match has no effect on the PWM output signal generation. The typical setup to obtain a trigger with a flag is to enable DMA and drive the DMA acknowledgement or DMA completion input high.

AS2 is not buffered, and therefore the UC updates it immediately. If the UC is running when you make a change, this could cause either of the following:

- The loss of one trigger event
- The generation of two trigger events within the same period

You access AS2 by reading or writing ALTA*n*[ALTA].

63.5.3.19.5 BS1 and BS2 in OPWMT mode

You access BS1 and BS2 using B*n*[B]:

- When you read B*n*[B], you read BS1.
- When you write to B*n*[B], you write to BS2.

BS1 defines the trailing edge of the PWM pulse output, and therefore the duty cycle of the PWM signal. To synchronize the BS1 update with the PWM signal and to ensure a correct output pulse generation, the BS2→BS1 transfer occurs at every AS1 match. This behavior is the same as in OPWM mode with next-period update.

Output Update Disable (OUDIS) affects transfers between BS2 and BS1 only.

63.5.3.19.6 Force match

At any time, Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on AS1 or BS1, respectively. Similarly to a BS1 match, Force Match B changes the internal counter to 1h. The force-match operations do not set the input-capture flag (S*n*[FLAG]). Any match resulting from writing 1 to FORCMA or FORCMB has priority over any simultaneous match regarding output pin transitions. BS2→BS1 transfer at an A match is not inhibited by writing 1 simultaneously to both FORCMA or FORCMB. If you write 1 to both FORCMA and FORCMB simultaneously, the output pin acquires the complement of C*n*[EDPOL], as if AS1 and BS1 had the same value. FORCMA assertion causes the UC to process the BS2→BS1 transfer as a regular A match comparison and not due to FORCMA assertion, regardless of FORCMB assertion. If subsequent matches occur on comparators AS1 and B, the UC continues to generate PWM pulses, regardless of the state of S*n*[FLAG].

63.5.3.19.7 Duty cycle

To achieve 0% duty cycle, you must write the same value to AS1 and BS2. When a simultaneous match on comparators A and B occurs, the UC drives the complement of C*n*[EDPOL] on the output flip-flop at every period.

To achieve 100% duty cycle, you must write a value to BS1 that is greater than the maximum value of the selected timebase. The maximum counter value for the timebase is FF_FFFEh for a 24-bit counter and FFFEh for a 16-bit counter. When a match on comparator AS1 occurs, the UC drives C*n*[EDPOL] on the output flip-flop at every period. The match at comparator A still triggers the BS2→BS1 transfer.

Timing example: 0% duty cycle illustrates the UC running in OPWMT mode with trigger-event generation and a 0% duty cycle.

Timing example: 100% duty cycle illustrates the UC running in OPWMT mode with trigger-event generation and a 100% duty cycle.

63.5.3.19.8 Timing example: 0% duty cycle

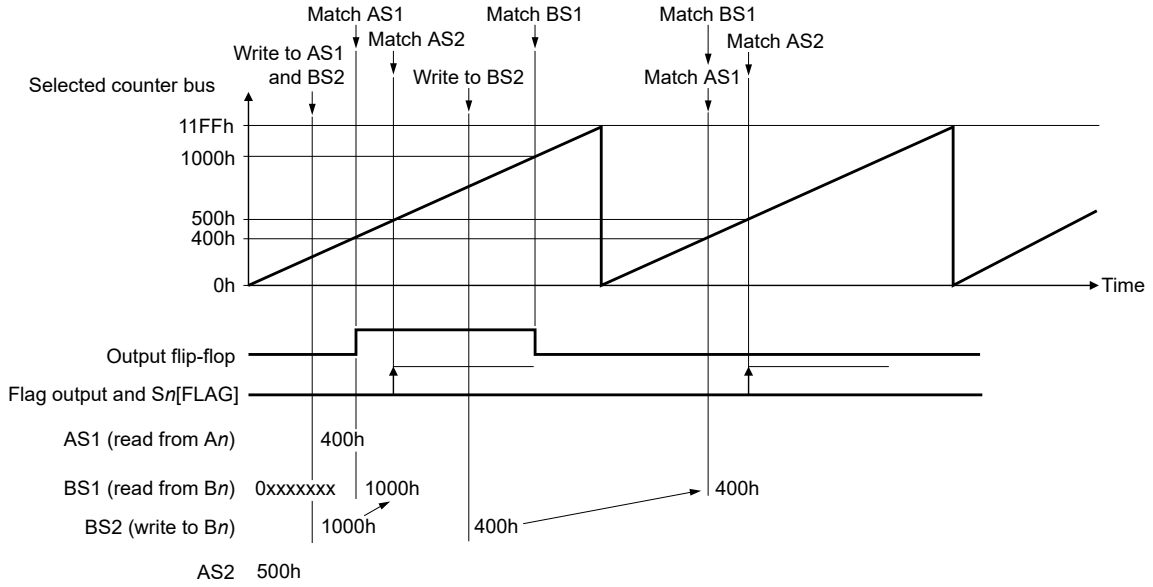

Figure 361. Timing example: 0% duty cycle

63.5.3.19.9 Timing example: 100% duty cycle

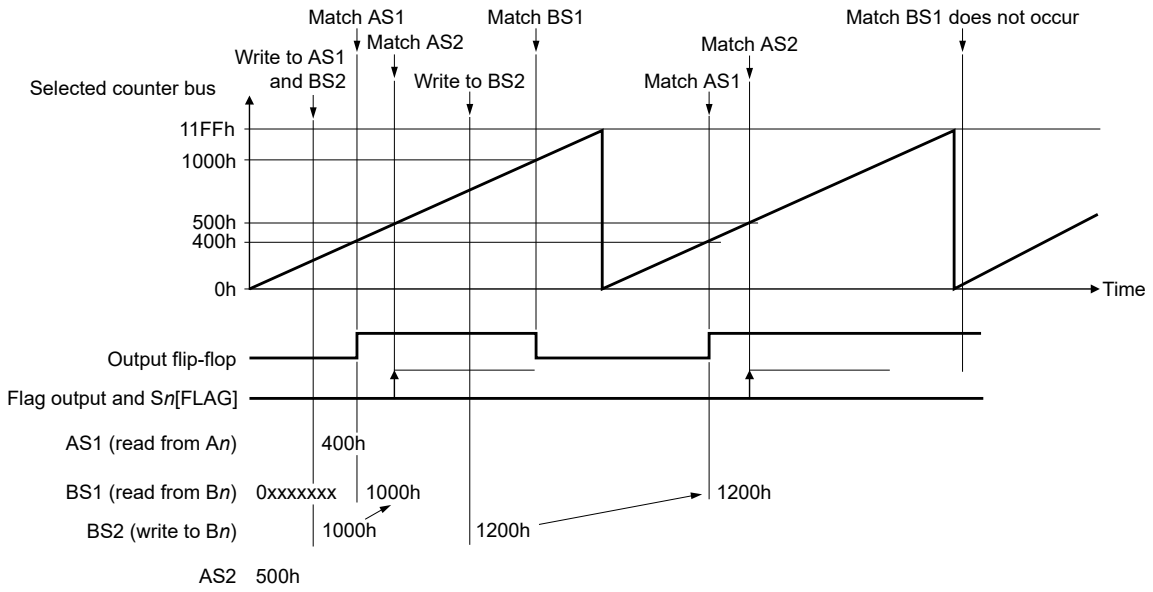

Figure 362. Timing example: 100% duty cycle

63.5.3.19.10 Output disable

As with other UC modes, OPWMT mode implements the output-disable function. When C*n*[ODIS] = 1, assertion of the output-disable input causes the UC to drive C*n*[EDPOL] on the output. Other than the fixed output, the UC continues to operate normally. When the output-disable signal deasserts, the UC returns to full normal operation.

63.5.3.20 Programmable input filter (PIF)

63.5.3.20.1 Overview

The PIF specifies the minimum input pulse width, in clock cycles, that can pass through the filter. It supports bypass operation (C*n*[IF]), with the input signal synchronized before arriving at the digital filter, or from 2 to 16 clock cycles in powers of 2.

63.5.3.20.2 Counter

The PIF is a 5-bit programmable up counter. The selected clock source increments the up counter after the number of clock cycles specified by the input filter (C*n*[IF]0.

The system clock synchronizes the input signal. When this signal changes state, the counter begins incrementing. As long as the new signal state is stable, the counter continues incrementing. If the counter overflows, eMIOS validates the new signal value. In this case, it transmits the value as a pulse edge to the edge detector. If the opposite edge appears on the signal before validation (overflow), eMIOS resets the counter. At the next transition, the counter starts incrementing again. A glitch does not occur on the edge detector for any pulse shorter than the full range of the masked counter.

Neither Freeze state nor deasserted GTBE disables the filter.

63.5.3.20.3 UC PIF logic

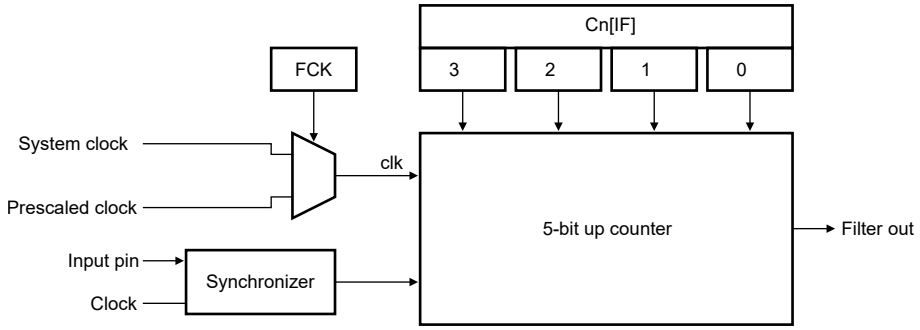

Figure 363. UC PIF logic

63.5.3.20.4 Timing example: UC PIF at 4 cycles

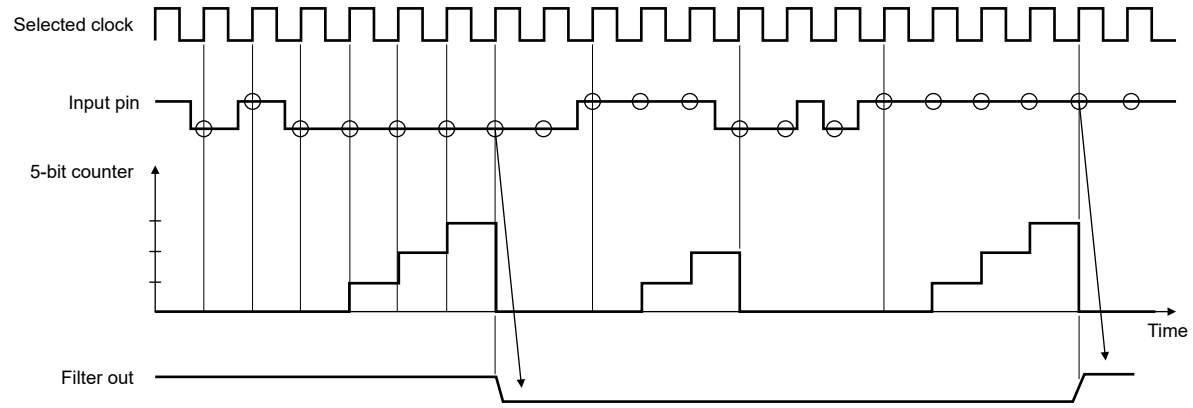

Figure 364. Timing example: UC PIF at 4 cycles

63.5.3.21 UC clock prescaler (CP)

eMIOS divides the GCP output signal by the UC CP (C*n*[UCPRE] + 1) to generate a clock enable for the UC internal counter. See Global clock prescaler (GCP). You enable the UC CP by writing 1 to C*n*[UCPREN]. If you disable the CP (write 0 to the same field), eMIOS stops the UC internal counter.

To ensure safe operation and avoid glitches, you must perform the following steps to change the UC CP:

1. Disable the GCP (write 0 to MCR[GPREN]).
2. Disable the UC CP (write 0 to C*n*[UCPREN]).
3. Specify the new prescaler value (write CP – 1 to C*n*[GPRE].
4. Enable the UC CP (write 1 to C*n*[UCPREN]).
5. Enable the GCP (write 1 to MCR[GPREN]).

63.5.4 Peripheral bus interface unit (BIU)

The BIU provides the interface between the IIB and the peripheral bus, which allows communication among all submodules and the IP interface. The BIU supports 8-, 16-, and 32-bit accesses performed over a 32-bit data bus in a single clock cycle.

63.5.5 Global clock prescaler (GCP)

eMIOS divides the system clock by the GCP (MCR[GPRE] + 1) and routes the resulting prescaled clock output to the channel CPs. You enable the GCP by writing 1 to MCR[GPREN]. If you disable the GCP (write 0 to the same field), eMIOS clears the prescaler counter and stops the prescaler clock.

To ensure safe operation and avoid glitches, you must perform the following steps to change the GCP:

1. Disable the GCP (write 0 to MCR[GPREN]).
2. Specify the new prescaler value (write GCP – 1 to MCR[GPRE].
3. Enable the GCP (write 1 to MCR[GPREN]).

63.5.6 Freeze and chip Debug mode

63.5.6.1 Enter and exit Freeze state

When the chip is in Debug mode (the chip Debug signal is asserted), you can freeze individual UCs. For the effects of Freeze state on eMIOS functions, see Freeze effects.

To put a channel in Freeze state, you must meet all of the following conditions:

- The chip must assert Debug.
- Prepare eMIOS for the Freeze state (write 1 to MCR[FRZ]).
- Enable Freeze for each channel you want to freeze:
  - Write 1 to C*n*[FREN].

A channel exits Freeze state when any of the following conditions occur:

- The chip deasserts Debug.
- You take eMIOS out of the Freeze state (write 0 to MCR[FRZ]).
- You disable Freeze for the channel:
  - write 0 to C*n*[FREN].

63.5.6.2 Freeze effects

Function	Effects of freeze
GCP	No effect
UC	• Halts counter, capture, and compare operation. • Freezes UC in its current state. • Makes all registers accessible. • In output modes, force match remains operational, allowing software to force the output to the desired level. • In input modes, the UC ignores input events. • When eMIOS exits Freeze state then UC operations resume, but they may be inconsistent until the UC reenters GPIO mode.
STAC	No effect
BIU	No effect

63.6 Initialization information

When initializing eMIOS, take the following considerations into account.

For eMIOS behavior on reset, see Reset.

Before changing the UC operating mode, you must:

1. Put the UC in GPIO mode (write 0b or 1b to C*n*[MODE]).
2. Write the correct values for the next operating mode to A*n* and B*n*.
3. Put the UC in the new operating mode (write the appropriate value to C*n*[MODE]).

If you change a UC from one mode to another without performing this procedure, the first operation cycle of the selected timebase can be random; that is, matches can occur in random time because you did not update A*n* and B*n* with correct values before the timebase matches the previous contents of either register.

When you enable interrupts, any interrupt service routine must clear the flag before exiting.

63.7 Application information

63.7.1 Overview

All output operation modes can generate correlated output signals. You can disable updates of the output signals for each UC (OUDIS).

To guarantee that incrementing of the internal counters of correlated channels occurs in the same clock cycle, you must configure the internal CPs before enabling the GCP. If you configure the internal CPs after enabling the GCP, the internal counters may increment in the same ratio, but at different clock cycles.

You should drive the Output Disable Input signals with the flag signals of some UCs running in SAIC mode. When an output disable condition happens, the interrupt service routine must process the output channels before processing the channels running SAIC. This sequence avoids glitches in the output pins.

63.7.2 Timebase generation

In the MC and OPWFM modes with internal clock sources, you can modify the internal counter rate by configuring the CP ratio. Timebase with the fastest prescaler ratio illustrates a timebase with a prescaler ratio of one.

NOTE

The buffered modes, MCB and OPWFMB, behave differently.

If the prescaler ratio is greater than one or you select an external clock, the internal counter behaves in one of four different ways depending on the channel mode:

- In MC mode with Clear on Match Start and External Clock: Timebase generation with clear on match start and external clock.
- In MC mode with Clear on Match Start and Internal Clock source: Timebase generation with clear on match start and internal clock.
- In MC mode with Clear on Match End: Timebase generation with clear on match end.
- In OPWFM mode: Timebase generation with clear on match start and internal clock. The internal counter clears at the start of the match signal, skips the next prescaled clock edge, and then increments in the subsequent prescaled clock edge.

63.7.3 Timebase with the fastest prescaler ratio

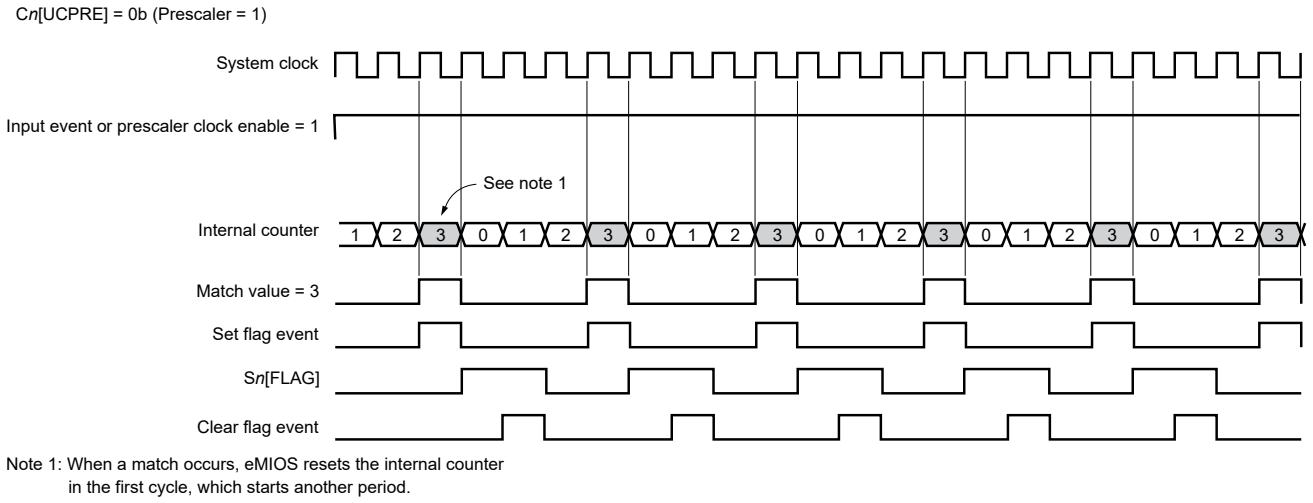

Figure 365. Timebase with fastest prescaler ratio

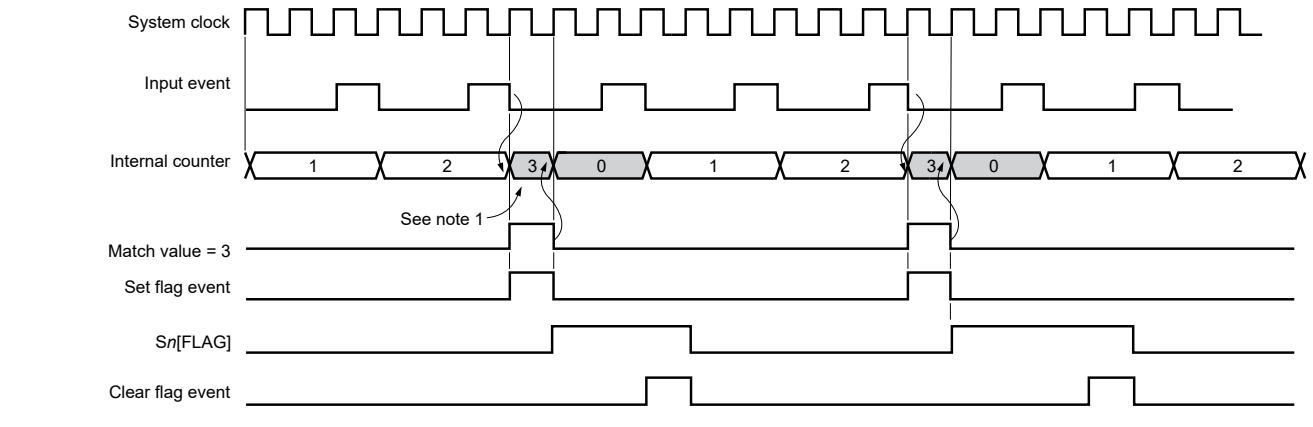
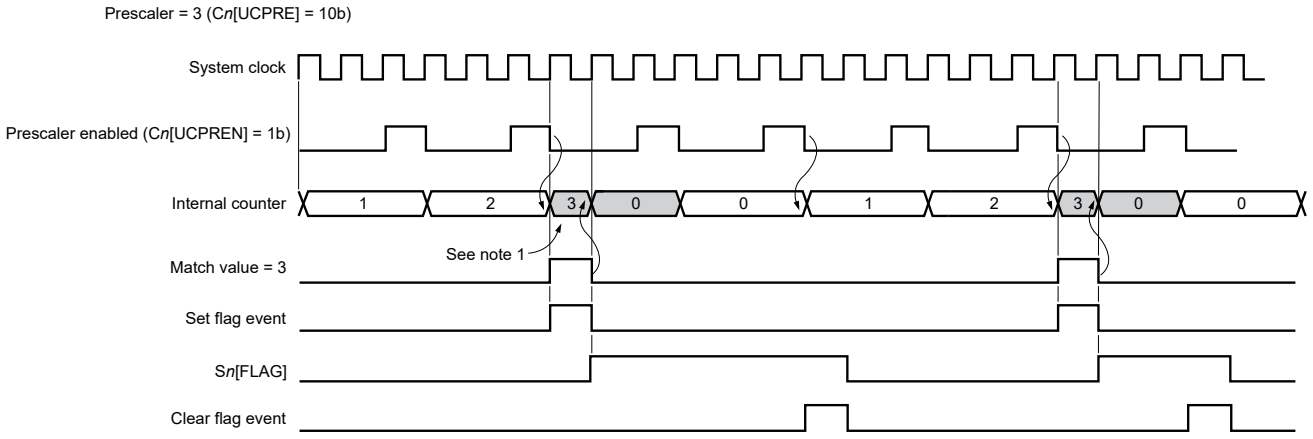
63.7.4 Timebase generation with clear on match start and external clock



Note 1: When a match occurs, eMIOS resets the internal counter in the first clock cycle.
The counter starts counting at the next edge of the prescaler clock enable.

Figure 366. Timebase generation with clear on match start and external clock

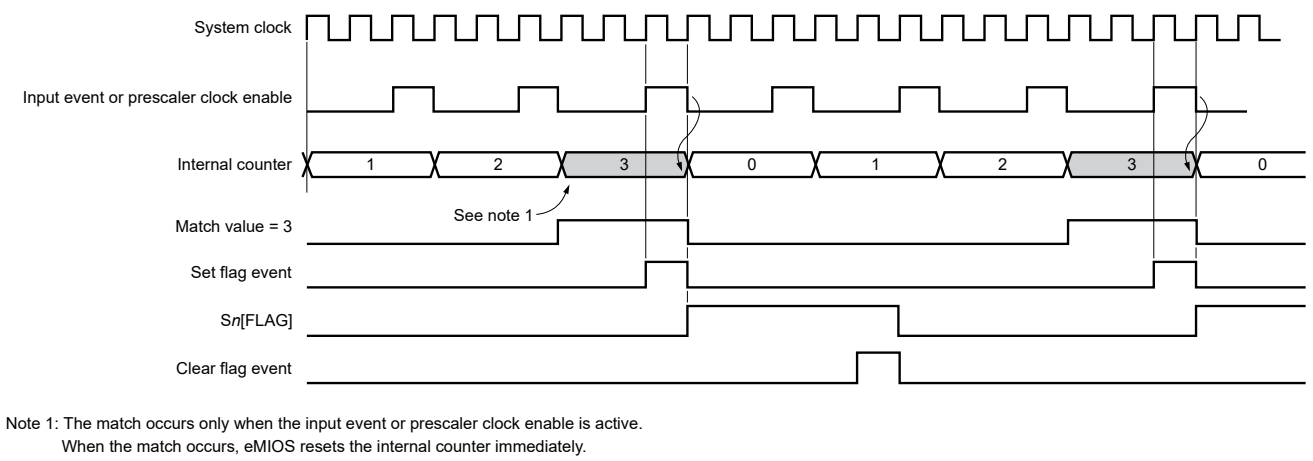
63.7.5 Timebase generation with clear on match start and internal clock



Note 1: When a match occurs, eMIOS clears the internal counter in the first clock cycle.
The counter starts counting again only after the second edge of the prescaled clock.

Figure 367. Timebase generation with clear on match start and internal clock

63.7.6 Timebase generation with clear on match end



Note 1: The match occurs only when the input event or prescaler clock enable is active.
When the match occurs, eMIOS resets the internal counter immediately.

Figure 368. Timebase generation with clear on match end

63.7.7 Coherent accesses

Reading A*n*[A] again in the same period as the last read of B*n*[B] results in incoherent results if the last read of B*n*[B] occurred after a disabled BS2→BS1 transfer.

63.7.8 Initializing channels and modes

Perform the following basic steps for output mode startup. This procedure assumes the channels are initially in GPIO mode:

1. Disable the GPC (write 0 to MCR[GPREN]).
2. For each timebase UC:
   a. Disable the CP (write 0 to C*n*[UCPREN]).
   b. Write an initial value to the internal counter (CNT*n*[C]).
   c. Write initial values to A*n*[A] and B*n*[B].
   d. Configure the UC for MC or MCB Up mode (write the appropriate value to C*n*[MODE]).
   e. Select the CP ratio (C*n*[UCPRE]).
   f. Enable the CP (write 1 to C*n*[UCPREN]).
3. For each output UC:
   a. Disable the CP (write 0 to C*n*[UCPREN]).
   b. Write initial values to A*n*[A] and B*n*[B].
   c. Select the timebase input (C*n*[BSL]).
   d. Specify the output mode (write the appropriate value to C*n*[MODE]).
   e. Select the same CP ratio as the timebase UC (C*n*[UCPRE]).
   f. Enable the CP (write 1 to C*n*[UCPREN]).
4. Enable the GPC (write 1 to MCR[GPREN]).
5. Enable GBTE (write 1 to MCR[GBTE]).

The timebase channel and the output channel may be the same for some applications such as in OPWFM or OPWFMB mode, or whenever the output channel drives the timebase itself.

You may configure flags at any time.

63.8 Memory maps and registers

63.8.1 Overall address map organization

All address locations not explicitly mentioned in this table are reserved. When you access an absent register, absent channel, or reserved address space, the transfer terminates with an error.

Table 415. Overall address map organization

Base address (hex)	Description
0	Module Configuration (MCR)
4	Global Flag (GFLAG)
8	Output Update Disable (OUDIS)
C	Disable Channel (UCDIS)
20	Channels 0–7
120	Channels 8–15
220	Channels 16–23

63.8.2 UC memory overview

Table 416. UC memory overview

Offset from UC *n* base address (hex)	Description
0	UC A n (A0 - A23)
4	UC B n (B0 - B23)
8	UC Counter n (CNT0 - CNT23)
C	UC Control n (C0 - C23)
10	UC Status n (S0 - S23)
14	Alternate Address n (ALTA0 - ALTA23)
18	UC Control 2 n (C2_0 - C2_23)
1C–1F	Reserved

63.8.3 AS1, AS2, BS1, and BS2 shadow registers

When you use eMIOS UC modes, you rely heavily on four shadow registers:

- AS1
- AS2
- BS1
- BS2

You use A*n*[A], B*n*[B], and ALTA*n*[ALTA] to access these shadow registers:

- Each instance of A*n*[A] has a separate associated instance of AS1 and AS2. In some UC modes, you also use ALTA*n*[ALTA] to access AS2.
- Each instance of B*n*[B] has a separate associated instance of BS1 and BS2.

See Relationship between A*n*, B*n*, ALTA*n*, and shadow registers.

Each UC mode uses the AS1-AS2 and BS1-BS2 shadow register pairs for various match and capture functions, as described in Unified channels (UC).

A reset clears all shadow registers.

Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] describes how you write to and read from the shadow registers for all operation modes. Values not listed are reserved. For more information, see Unified channels (UC).

63.8.4 Relationship between A*n*, B*n*, ALTA*n*, and shadow registers

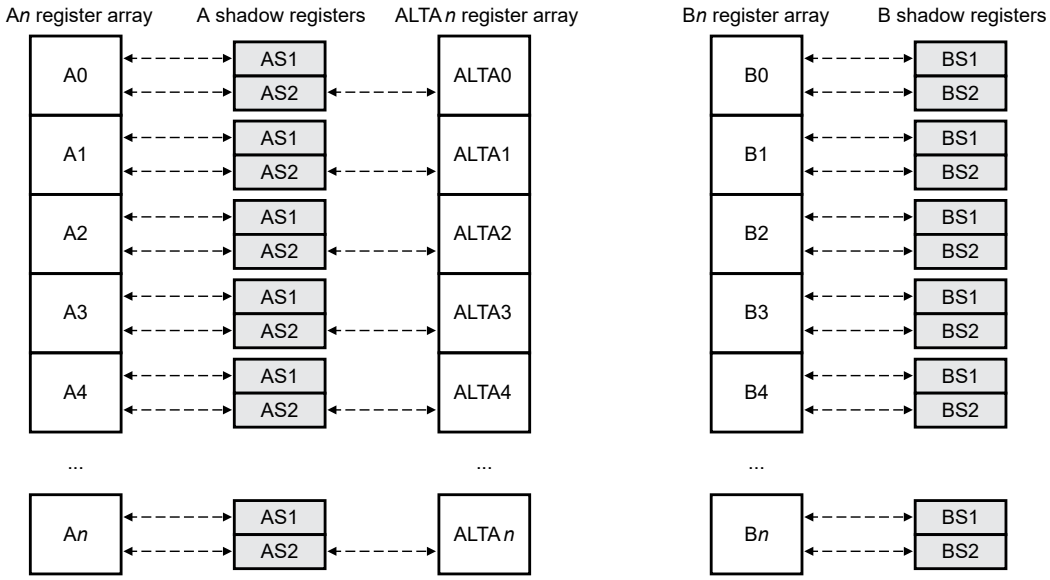


Figure 369. Relationship between A*n*, B*n*, ALTA*n*, and shadow registers

63.8.5 Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA]

This table describes how you write to and read from the following registers for all operation modes:

- UC A n (A0 - A23)
- UC B n (B0 - B23)
- Alternate Address n (ALTA0 - ALTA23)

Values not listed are reserved. For more information, see Unified channels (UC).

Table 417. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA]

Operation mode	Register access					
	A*n*		B*n*		ALTA*n*	
	Write	Read	Write	Read	Write	Read
GPIO	AS1 and AS2[1]	AS1	BS1 and BS2[2]	BS1	AS2	AS2

Table continues on the next page...

Table 417. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] (continued)

Operation mode	Register access					
	A*n*		B*n*		ALTA*n*	
	Write	Read	Write	Read	Write	Read
SAIC[3]	—	AS2	BS2	BS2	—	—
SAOC[3]	AS2	AS1	BS2	BS2	—	—
IPWM	—	AS2	—	BS1	—	—
IPM	—	AS2	—	BS1	—	—
DAOC	AS2	AS1	BS2	BS1	—	—
PEA	AS1	AS2	—	BS1	—	—
PEC[3]	AS1	AS1	BS1	BS1	—	AS2
WPTA	AS1	AS1	BS1	BS1	—	AS2
MC[3]	AS2	AS1	BS2	BS2	—	—
OPWFM	AS2	AS1	BS2	BS1	—	—
OPWMC	AS2	AS1	BS2	BS1	—	—
OPWM	AS2	AS1	BS2	BS1	—	—
OPWMT	AS1	AS1	BS2	BS1	AS2	AS2
MCB[3]	AS2	AS1	BS2	BS1	—	—
OPWFMB	AS2	AS1	BS2	BS1	—	—
OPWMCB	AS2	AS1	BS2	BS1	—	—
OPWMB	AS2	AS1	BS2	BS1	—	—

1. This operation writes the same value to AS1 and AS2.
2. This operation writes the same value to BS1 and BS2.
3. These modes do not require UC B n (B0 - B23), but you can still use it to access BS2.

63.8.6 eMIOS register descriptions

All control registers are 32 bits wide. Data fields are 24 bits wide. There are 24 UCs, as mapped in Counter buses, channels, and timebase sources.

63.8.6.1 eMIOS memory map

eMIOS_0 base address: 4008_8000h

63.8.6.2 Module Configuration (MCR)

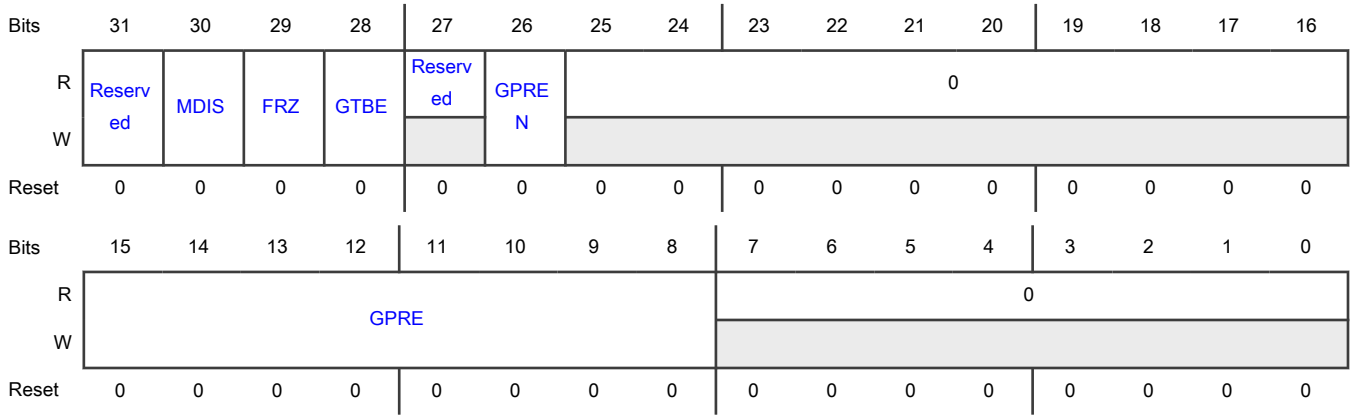
Offset

Register	Offset
MCR	0h

Function

Configures eMIOS operation.

Diagram



Fields

Field	Function
31 —	Reserved Write only the reset value to this field.
30 MDIS	Module Disable Disables eMIOS by stopping the clock.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When you disable eMIOS, its clock stops, it consumes less power, and you can access only the following registers: • Module Configuration (MCR) • Output Update Disable (OUDIS) • Disable Channel (UCDIS) 0b - Enable 1b - Disable
29 FRZ	Freeze Prepares eMIOS to enter Freeze state (see Freeze and chip Debug mode). eMIOS does not enter Freeze state until both of the following conditions occur: • The chip asserts Debug mode. • You enable Freeze for each UC (write 1 to C*n*[FREN]). A channel remains frozen until one or more of the following occur: • You force eMIOS to exit the Freeze state (write 0 to FRZ). • The chip deasserts Debug mode. • You disable Freeze for that UC (write 0 to C*n*[FREN]). 0b - Exit Freeze state 1b - Enter Freeze state
28 GTBE	Global Timebase Enable Asserts the GTBE_OUT signal. If GTBE_OUT is connected to the GTBE_IN input of one or more eMIOS instances, asserting the signal turns on the internal counters of those eMIOS instances simultaneously. **NOTE** The GTBE_IN input enables (asserted) or disables (deasserted) the internal counters. 0b - Deassert GTBE_OUT 1b - Assert GTBE_OUT
27 —	Reserved
26 GPREN	Global Prescaler Enable Enables the global prescaler counter. Disabling the global prescaler clears the prescaler counter and stops the prescaler clock. 0b - Disable 1b - Enable
25-16	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
15-8 GPRE	Global Prescaler Specifies the global clock prescaler. Write the desired clock divide ratio minus 1. For example, for a divide ratio of 8, write 111b. The prescaler can range from 1 (0b) to 256 (11111111b).
7-0 —	Reserved

63.8.6.3 Global Flag (GFLAG)

Offset

Register	Offset
GFLAG	4h

Function

Groups the flag fields from all channels into one register to improve interrupt handling.

For UCs, each field mirrors the corresponding channel flag (S*n*[FLAG]).

Diagram

63.8.6.4 Output Update Disable (OUDIS)

Offset

Register	Offset
OUDIS	8h

Function

Disables transfers from AS2 to AS1 and BS2 to BS1 on a per-channel basis. This applies to any channel operating in MC, MCB, or any output mode that writes to AS2 and BS2.

When a field is 0, transfers on that channel occur immediately or in the next period, depending on the operation mode. Unless that mode's description states otherwise, the transfer occurs immediately.

63.8.6.6 UC A n (A0 - A23)

Offset

For n = 0 to 23:

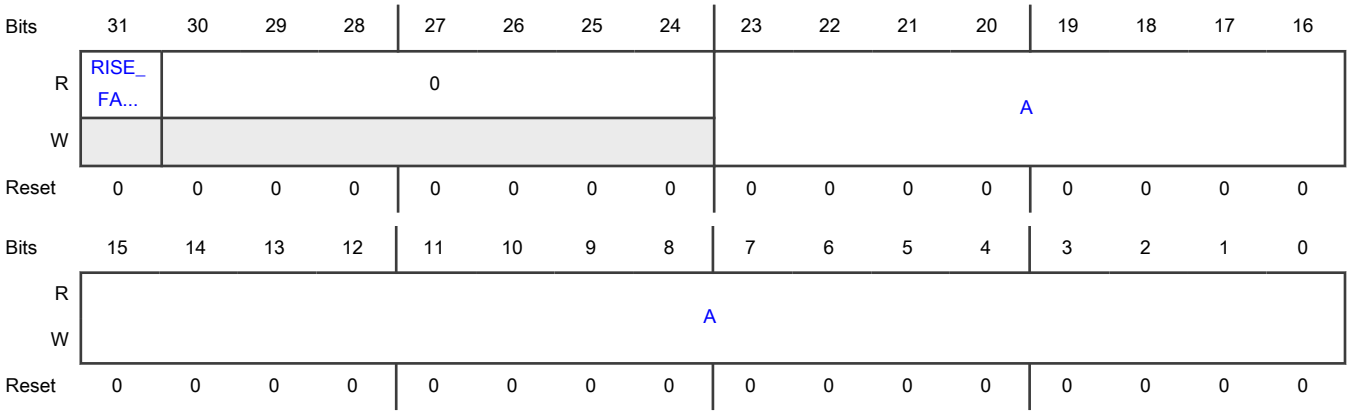
Register	Offset
An	20h + (n × 20h)

Function

Accesses the AS1 and AS2 shadow registers for each UC, depending on the selected UC mode. See AS1, AS2, BS1, and BS2 shadow registers.

For information about how you write to and read from A*n*, B*n*, and ALTA*n* for all UC modes, see Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA].

Diagram



Fields

Field	Function
31 RISE_FALL	Rising and falling edge detection Indicates rising and falling edge in SAIC sub-mode.

Table continues on the next page...

63.8.6.8 UC Counter n (CNT0 - CNT23)

Offset

Register	Offset
CNT0	28h
CNT1	48h
CNT2	68h
CNT3	88h
CNT4	A8h
CNT5	C8h
CNT6	E8h
CNT7	108h
CNT8	128h
CNT16	228h
CNT22	2E8h
CNT23	308h

Function

Indicates the value of the UC internal counter.

When eMIOS is in GPIO mode or the UC is frozen, this register is read-write. For all other modes, this register is read-only. When entering some UC modes, eMIOS automatically clears this register. See Unified channels (UC) for details.

The following modes use the UC counter:

- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode
- Pulse Edge Counting (PEC) mode
- Modulus Counter (MC) mode
- Modulus Counter Buffered (MCB) mode

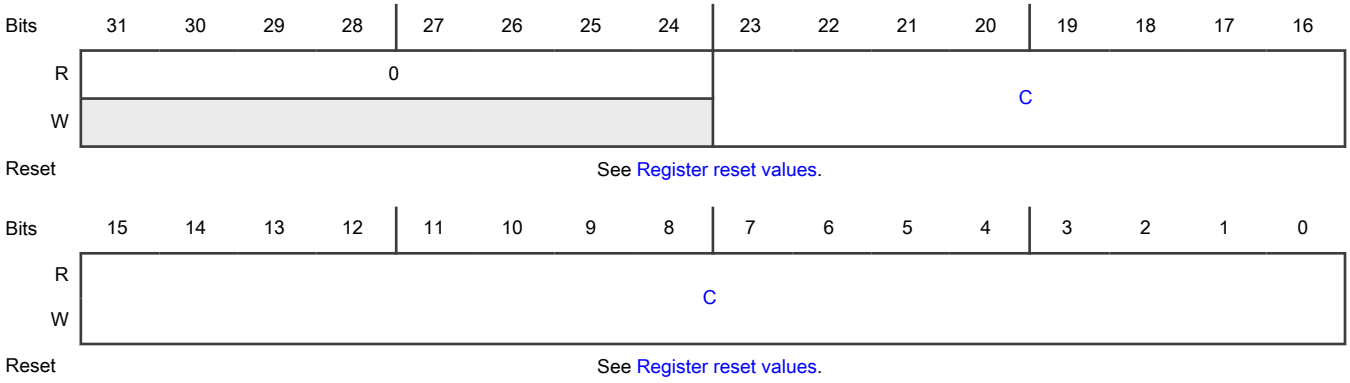
All other modes not in this list do not use the internal counter.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
eMIOS_0	CNT0–CNT8 CNT16 CNT22–CNT23	—
eMIOS_1	CNT0 CNT8 CNT16 CNT22–CNT23	CNT1–CNT7
eMIOS_2	CNT0 CNT8 CNT16 CNT22–CNT23	CNT1–CNT7

Diagram



Register reset values

Register	Reset value

Table 418. MODE field values (continued)

UC mode	MODE (binary)
MCB (up counter)	101_000p[1]
Reserved	101_001p
MCB (up or down counter)	101_01pp[1]
OPWFMB	101_10p0[1]
Reserved	101_10p1
OPWMCB (with trailing edge dead time)	101_11p0[1]
OPWMCB (with leading edge dead time)	101_11p1[1]
OPWMB	110_00p0[1]
Reserved	110_0001–111_1111

1. p = Adjust parameters for the mode of operation. See Unified channels (UC) for details.

Table 419. Edge Polarity (EDPOL) settings

For these modes:	EDPOL does this:	and EDPOL values mean:
Input	Selects which edge triggers the internal counter, an input capture, or the input capture flag. If EDPOL does not appear in the UC mode description, it has no effect on UC operation.	0b - Trigger on a falling edge 1b - Trigger on a rising edge
Output	Selects the logic level on the output pin.	0b - A match on comparator A deasserts the output flip-flop, while a match on comparator B sets it 1b - A match on comparator A asserts the output flip-flop, while a match on comparator B clears it

Table 420. Edge Select (EDSEL) settings

For these modes:	EDSEL does this:	and EDSEL values mean:
Input	Selects whether the internal counter is triggered by both edges of a pulse or by a single edge as defined by EDPOL. If EDSEL does not appear in the UC mode description, it has no effect on UC operation.	0b - Single-edge triggering on edge specified in EDPOL 1b - Both-edges triggering
GPIO in	Selects whether an edge asserts the input capture flag (S*n*[FLAG]).	0b - Sets S*n*[FLAG] on the edge specified in EDPOL 1b - Does not set S*n*[FLAG]
SAOC	Selects the behavior of the output flip-flop at each match.	0b - Drive the EDPOL value on the output flip-flop 1b - Toggle output flip-flop

Fields

Field	Function
31 FREN	Freeze Enable Enables putting the UC in Freeze state. See Freeze and chip Debug mode. 0b - Disable 1b - Enable
30 ODIS	Output Disable Disables the output pin when running any of the output modes except GPIO. When you assert ODIS: • If the selected Output Disable Input signal asserts, the output pin reflects: — For OPWFMB and OPWMB modes, EDPOL (see Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode and Output PWM Buffered (OPWMB) mode). — For all other modes, the complement of EDPOL, but the UC continues to operate normally—it continues to generate flags and matches. • If the selected Output Disable Input signal deasserts, the output pin operates normally. 0b - Enables output pin (the output pin operates normally) 1b - Disables output pin
29-28 ODISSL	Output Disable Select Selects one of four output disable input signals. 00b - 0 01b - 1 10b - 2 11b - 3
27-26	Prescaler Selects the clock divider value for the UC internal prescaler.

Table continues on the next page...

Table continued from the previous page...

Field	Function
UCPRE	**NOTE** The two least-significant bits of C2_*n*[UCEXTPRE] mirror UCPRE. Any write to UCPRE also affects UCEXTPRE. 00b - 1 01b - 2 10b - 3 11b - 4
25 UCPREN	Prescaler Enable Enables the prescaler counter. 0b - Disable (no clock) 1b - Enable
24 DMA	Direct Memory Access Selects whether the input capture flag (S*n*[FLAG]) or overrun (S*n*[OVR]) triggers an interrupt or DMA request. 0b - Interrupt request 1b - DMA request
23 —	Reserved
22-19 IF	Input Filter Selects the minimum input pulse width, in filter clock cycles, that can pass through the input filter. This field does not apply to output modes. The filter latency—the difference in time between the input and the response—is three clock edges. 0000b - Bypassed; the input signal is synchronized before arriving at the digital filter 0001b - 2 cycles 0010b - 4 cycles 0100b - 8 cycles 1000b - 16 cycles All other values are reserved.
18 FCK	Filter Clock Select Selects the clock source for the programmable input filter. 0b - Prescaled clock 1b - eMIOS module clock

Table continues on the next page...

Table continued from the previous page...

Field	Function
17 FEN	Flag Enable Enables the input capture flag (S*n*[FLAG]) to generate an interrupt request or a DMA request, as selected in DMA. 0b - Disable 1b - Enable
16-14 —	Reserved
13 FORCMA	Force Match A For output modes, asserting Force Match A causes the comparator to report a successful comparison on comparator A regardless of whether a comparison actually occurred. It does not set the input capture flag (S*n*[FLAG]). This field always reads 0. This bit is meaningful for every output operation mode that uses comparator A. Otherwise it has no effect. 0b - No effect 1b - Force a match at comparator A
12 FORCMB	Force Match B For output modes, asserting Force Match B causes the comparator to report a successful comparison on comparator B regardless of whether a comparison actually occurred. It does not set the input capture flag (S*n*[FLAG] does not become 1). This field always reads 0. This field applies only if the UC is in one of the following output modes. • Single Action Output Capture (SAOC) mode • Double Action Output Compare (DAOC) mode • Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode • Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode • Output PWM Buffered (OPWMB) mode • Output PWM with Trigger (OPWMT) mode This field has no effect in all other modes. 0b - No effect 1b - Force a match at comparator B
11 —	Reserved
10-9 BSL	Bus Select Selects one of the counter buses or the internal counter for the UC. Not all chips support all counter buses. See the chip-specific eMIOS information for details. 00b -

8 EDSEL	Edge Selection Controls several functions as shown in Table 420.
7 EDPOL	Edge Polarity Controls several functions as shown in Table 419.
6-0 MODE	Mode Selection Selects the UC mode as shown in Table 418. **NOTE** If you write a reserved value to this field, the results are unpredictable. When you change the value of MODE, you must first enter GPIO mode to reset the UC's internal functions. Failure to do this can result in invalid and unexpected output compare or input capture results or incorrectly set input capture flags (S*n*[FLAG]).

63.8.6.10 UC Status n (S0 - S23)

Offset

For n = 0 to 23:

Register	Offset
Sn	30h + (n × 20h)

Function

Indicates the status of the UC input-output signals and the overflow condition of the internal counter.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

63.8.6.11 Alternate Address n (ALTA0 - ALTA23)

Offset

For n = 0 to 23:

Register	Offset
ALTAn	34h + (n × 20h)

Function

Provides an alternate address to access AS2 shadow registers in these restricted modes:

- General-Purpose Input and Output (GPIO) mode
- Pulse Edge Counting (PEC) mode
- Output PWM with Trigger (OPWMT) mode

In these modes, you can use A*n*[A] together with ALTA*n*[ALTA] to access both AS1 and AS2. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] summarizes the ALTA*n* writing and reading accesses for all ALTA*n* operation modes.

In modes that do not require this register, any write access is ignored and any read access returns unspecified data.

NOTE

You must clear triggers to BCTU after TRGMUX programming using TRGCFG_n[TRG_FLAG] bit.

64.2 Overview

BCTU accepts ADC conversion-request trigger inputs and routes those requests to one or more ADCs.

BCTU accepts the following trigger sources:

- Hardware triggers (outputs from on-chip timer modules)
- Software triggers through the SFTRGRn register

BCTU maps each trigger input to a Trigger Configuration (TRGCFG_0 - TRGCFG_71) register, which specifies the target ADC channel and other control data for the requested conversion.

You can configure a list of ADC channels, the CL, that processes a sequence of conversions in response to a single trigger input. See the Conversion list (CL) section.

BCTU stores each ADC conversion result for CPU access or routing to memory through DMA.

If the same ADC is targeted by multiple triggers, priority logic selects the next trigger to process from all active trigger inputs. See Priority of simultaneous triggers.

BCTU input trigger signals are level-sensitive; thus, if a logical level 1 is detected, an event is captured by the BCTU.

64.2.1 Block diagram

The following figure shows the top-level block diagram of BCTU.

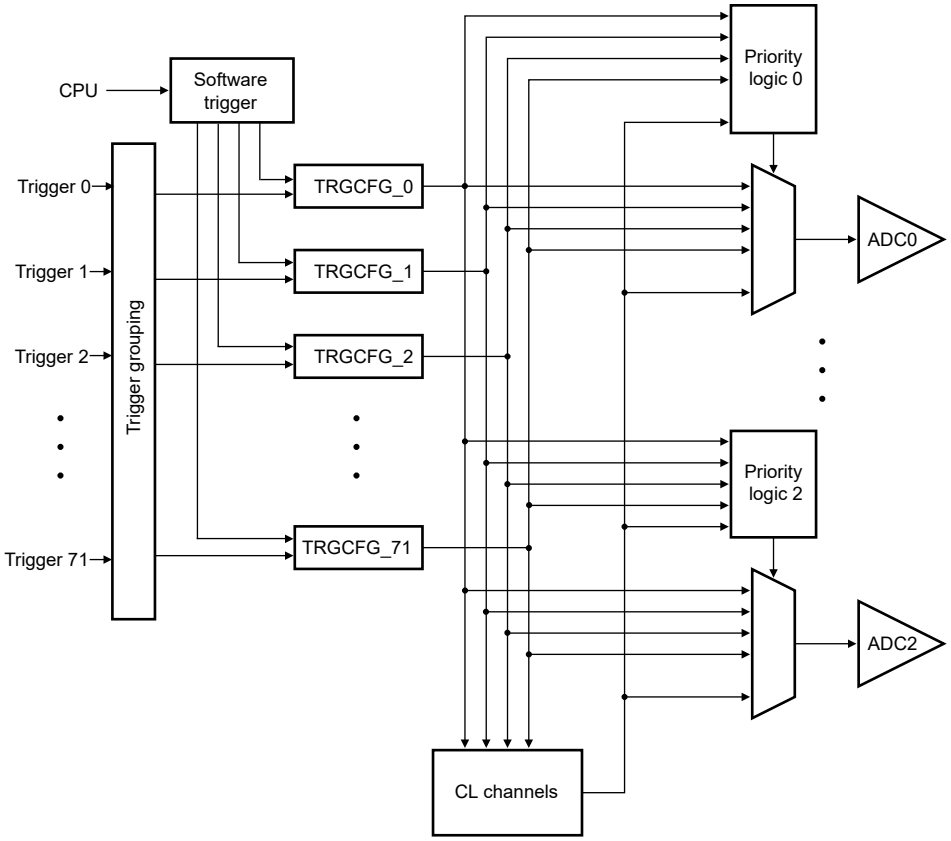

Figure 370. BCTU block diagram

64.2.2 Features

BCTU supports:

- 72 Trigger inputs, configured with the Trigger Configuration (TRGCFG_0 - TRGCFG_71) registers
- Trigger outputs to 3 ADCs
- One priority selection logic block per ADC
- Selection multiplexers to select one trigger at a time for each ADC
- A CL of 32 ADC channels
- A trigger grouping block to latch the hardware triggers. BCTU clears these triggers when the ADC sends an acknowledgement for conversion completion.

64.2.3 Interaction with other peripherals

BCTU works together with timer and ADC modules on the chip. Use the trigger configuration registers (TRGCFG_*n*) to map BCTU triggers to ADC inputs. When a timer output asserts a BCTU trigger, BCTU passes the trigger to an ADC input and stores the

trigger assertion until the corresponding ADC begins the requested conversion. When the ADC completes the conversion, BCTU asserts a trigger clear signal to clear both the internally stored trigger and the external trigger source if they are still asserted. Implementation illustrates the modules that interact with BCTU.

NOTE

A timer trigger can remain active until the corresponding ADC initiates conversion. Therefore, another match may occur in the timer before the ADC conversion begins. BCTU does not detect this trigger overrun. Your application must look for and respond to such conditions.

64.2.4 Implementation

The following figure shows the implementation structure of the BCTU.

NOTE

For more details of the actual trigger sources implemented in this device, see the chip-specific information section.

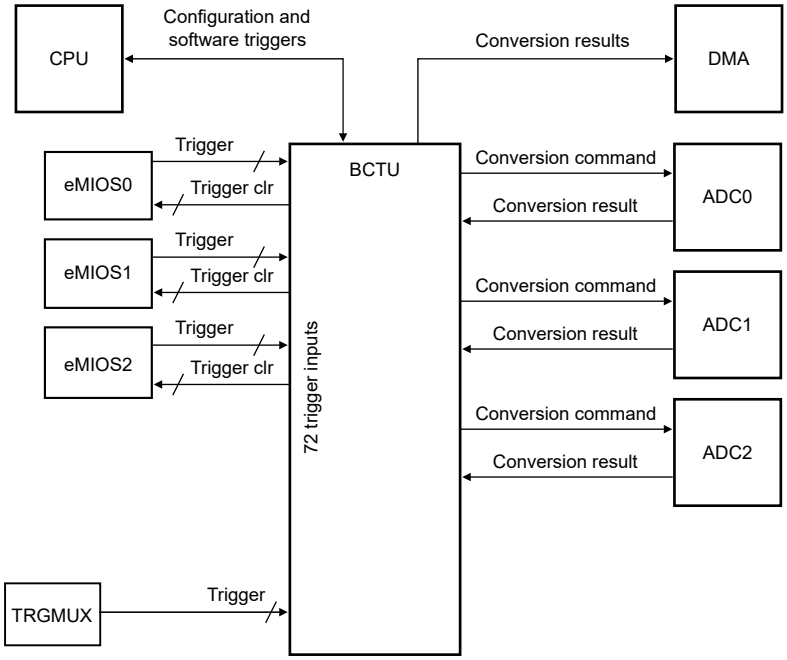

Figure 371. Implementation

64.3 Functional description

64.3.1 Triggers

64.3.1.1 Overview

BCTU prioritizes ADC trigger inputs based on the input number: the lower the number, the higher the priority associated with it. Therefore, trigger 0 is the highest priority trigger and trigger 71 is the lowest priority. The trigger input priority scheme determines which trigger takes precedence when more than one trigger occurs at the same time, or when the triggered ADC is busy with a conversion. Therefore, there are two possible scenarios for the trigger priority selection:

- When there are no ongoing conversions
- When a triggered ADC is executing a conversion

BCTU supports two types of trigger sources:

- Hardware triggers from timer modules
- Software triggers (SFTRGR*n*)

64.3.1.2 Hardware triggers

To request an ADC conversion through the BCTU, a timer module such as eMIOS asserts its output signal, which is connected to a BCTU trigger input. When BCTU detects the asserted trigger, it routes that request to the ADCs selected in the corresponding Trigger Configuration (TRGCFG_*n*[ADC_SEL*m*]). The trigger remains asserted until the requested conversion begins, at which time BCTU clears the trigger. If the timer asserts the trigger input when the trigger is already set, BCTU ignores the new trigger. If BCTU receives a new trigger input at the same time it is clearing the trigger, then the trigger remains asserted and BCTU initiates a new conversion.

If you configure the trigger for CL, trigger assertion begins a sequence of conversions controlled by the CL Channel Address (LISTCHR_0 - LISTCHR_15) registers. In this event, BCTU clears the trigger when the last conversion in the CL begins.

NOTE

Any new trigger input participates in the trigger priority selection scheme and therefore may not trigger the next conversion.

64.3.1.3 Software triggers

You assert a software trigger by writing 1 to the corresponding field of the appropriate software trigger (SFTRGR*n*) register. Similar to the hardware triggers, BCTU changes the software trigger field to 0 when the requested conversion begins. If you write 1 to the software trigger field while the conversion is still in progress, BCTU ignores the request. If you write 1 to the field at the same time BCTU is attempting to clear the trigger (change the field to 0), the trigger remains asserted and BCTU triggers a new conversion following the trigger priority criteria.

64.3.1.4 Configure all triggers

Global trigger enable (MCR[GTRGEN]) allows you to configure the BCTU trigger inputs and then activate them all at one time.

To configure and then activate all BCTU triggers:

1. Clear any currently active and asserted trigger inputs (write 0 to TRGFG_*n*[TRG_FLAG]), which also causes BCTU to assert trigger clear to the trigger sources.
2. Disable global triggers (MCR[GTRGEN]). This action deactivates all trigger inputs and prevents BCTU from generating any ADC conversion requests.
3. Configure the individual trigger inputs (see Configure individual triggers).
4. Enable global triggers (MCR[GTRGEN]). This action activates all individually enabled triggers at the same time.

64.3.1.5 Configure individual triggers

Using Trigger Configuration (TRGCFG_0 - TRGCFG_71), for each trigger:

- Enable the trigger (TRIGEN).
- Specify the target ADC (ADC_SEL*n*).
- Specify the ADC channel (CHANNEL_VALUE_OR_LADDR).
- Specify whether the trigger initiates a single conversion or a CL (TRS).
- For a CL trigger, specify a pointer to the CL element (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]).

64.3.1.6 Reconfigure triggers on-the-fly

NOTE

Reconfigure BCTU triggers only when the individual trigger is not active (TRG_FLAG). If TRG_FLAG is 1, the requested conversion is still in progress and it is not safe to modify the trigger configuration.

To reconfigure a trigger on-the-fly (while BCTU is in full operation):

1. Disable the trigger (TRIGEN) to prevent it from requesting a new conversion.
2. Check the current state of the trigger (TRG_FLAG) to be sure no conversion or CL is in progress.
3. When any in-progress conversion or CL completes (TRG_FLAG == 0), clear the trigger source by writing 1 to TRG_FLAG. This action ensures that only trigger inputs that assert after you reconfigure and re-enable the trigger are able to request a new conversion or CL.
4. Reconfigure the trigger (see Configure individual triggers).
5. Enable the trigger (TRIGEN).

64.3.1.7 Enable software triggers

To allow software triggers (SFTRGRn) to request conversions, you must enable global trigger enable (MCR[GTRGEN]). If you disable global trigger enable, software triggers do not initiate a conversion but asserted triggers remain asserted. However, when you enable global trigger enable, any asserted software triggers initiate conversions following the priority scheme of lowest to highest trigger number.

Software triggers operate regardless of individual trigger enable (TRGCFG_x[TRIGEN]). That is, writing 1 to any Software Trigger (SFTRGRn) initiates a conversion (following the priority scheme) regardless of the value of trigger enable. This software trigger independence supports the elimination of conflict between software and hardware triggers.

64.3.1.8 Trigger timing

There are four clock cycles from assertion of a BCTU trigger input to assertion of the trigger output to the ADC. For single conversions, BCTU asserts trigger clear back to the trigger source simultaneous to asserting the trigger to the ADC.

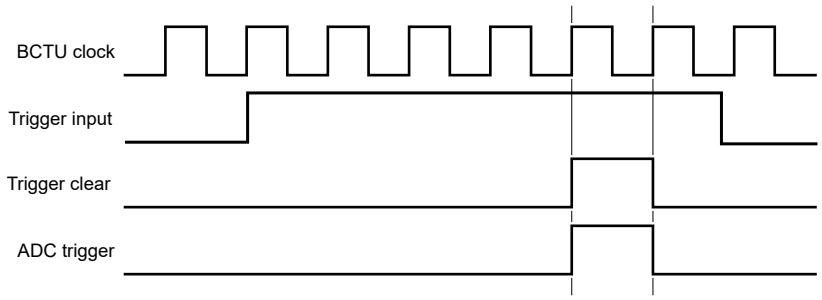

Figure 372. Trigger timing

64.3.1.9 Priority of simultaneous triggers

When more than one trigger input asserts a conversion request to the same ADC at the same time—that is, in the same BCTU clock cycle—BCTU employs a priority scheme to determine which asserted trigger to process next. BCTU prioritizes trigger inputs based on the trigger number. The lowest number, trigger 0, has the highest priority, and the highest number, trigger 71, has the lowest priority.

If two triggers assert in the same clock cycle, BCTU gives priority to the lower numbered trigger. For example, if trigger 0 and trigger 1 both assert in the same cycle, BCTU selects trigger 0 for trigger generation. Trigger 1 remains active (pending) until the conversion requested by trigger 0 completes. See Simultaneous trigger priority management.

If trigger 0 asserts again before the next trigger selection opportunity at the end of the current conversion, then BCTU selects it again and trigger 1 remains asserted (pending) during the next ADC conversion time frame.

As illustrated in Trigger timing, BCTU requires four clock cycles to transmit a conversion request to an ADC if that ADC is not already executing a conversion. However, if the ADC is busy at the time of trigger assertion, BCTU requires only three clock cycles to generate the conversion request for a subsequent conversion.

Triggers that assert in the same clock cycle but target different ADCs are not in conflict, and BCTU processes both triggers at the same time.

64.3.1.10 Simultaneous trigger priority management

The following figure shows the simultaneous triggers for priority management.

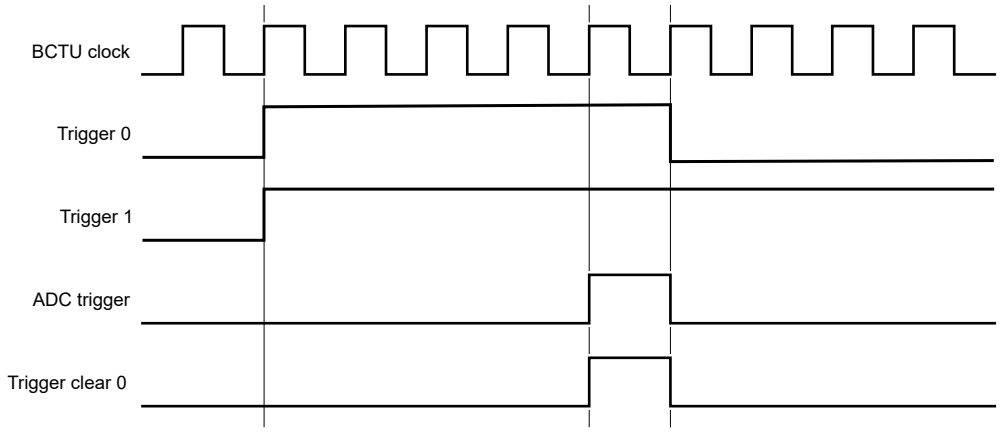

Figure 373. Simultaneous trigger priority management

64.3.1.11 Trigger management when ADC is busy

When a trigger input asserts a conversion request to an ADC that is already processing a conversion requested by a different trigger, the new trigger remains active (pending) until the conversion in progress completes. This behavior is the same as if the two triggers had been simultaneous (occurred in the same clock cycle). When the in-progress conversion completes, the pending trigger then competes for priority with any other active trigger for that ADC.

64.3.1.12 Trigger clearing mechanism

There are two sources of ADC conversion triggers: hardware trigger, from the trigger inputs and software triggers, from SFTRGRn register.

A logical level 1 is detected in the input and captured into an input trigger register. This register remains set until the related conversion starts. At this time, the input trigger register is cleared. If another logical level 1 is detected while the trigger register is already set, the new level is not considered by the BCTU hardware. If a new logical level 1 occurs at the same time the trigger register is being cleared, then the register remains set and a new conversion is triggered by this input.

NOTE

The new triggered conversion will participate in the trigger priority selection thus may not trigger the next conversion.

The software trigger behaves similarly to the hardware trigger. The difference is that the trigger register is set by a CPU write operation. The trigger register is cleared by the BCTU hardware when the related conversion starts. If the CPU tries to set the trigger register by writing to the SFTRGR register corresponding bit, while the register is already set, the new attempt to set the register is not considered by the BCTU hardware. If a set occurs at the same time the hardware is attempting to clear the same

trigger register, then the set has precedence and the register remains set. A new conversion will be triggered following the trigger priority criteria implemented in the hardware.

In case a LIST of conversions is triggered, instead of a single conversion, the trigger register is cleared at the start of the last conversion in the LIST.

64.3.2 Conversion list (CL)

64.3.2.1 CL overview

A CL executes a sequence of conversions on one or more target ADCs. See CL architecture and operation. It also stores information from the last conversion executed in a sequence except for the target ADC, which is stored in ADC select n (TRGCFG_*m*[ADC_SEL*n*]).

If the channel or CL address (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]) points to a CL element containing one or more entries:

1. The trigger initiates a sequence of conversions starting with the target CL element.
2. The sequence executes until the LAST channel (LISTCHR_*n*[LAST_y] is 1), and stops after that channel is converted.

When you configure the CL element for next channel wait for trigger (write 1 to LISTCHR_*n*[NEXT_CH_WAIT_ON_TRIG_y]):

1. BCTU clears the trigger source.
2. CL execution pauses after the current conversion is completed.
3. CL execution resumes when the same trigger asserts again.

BCTU determines trigger priority before executing any CL. See Priority of simultaneous triggers.

64.3.2.2 CL architecture and operation

The following figure shows the CL architecture and operation.

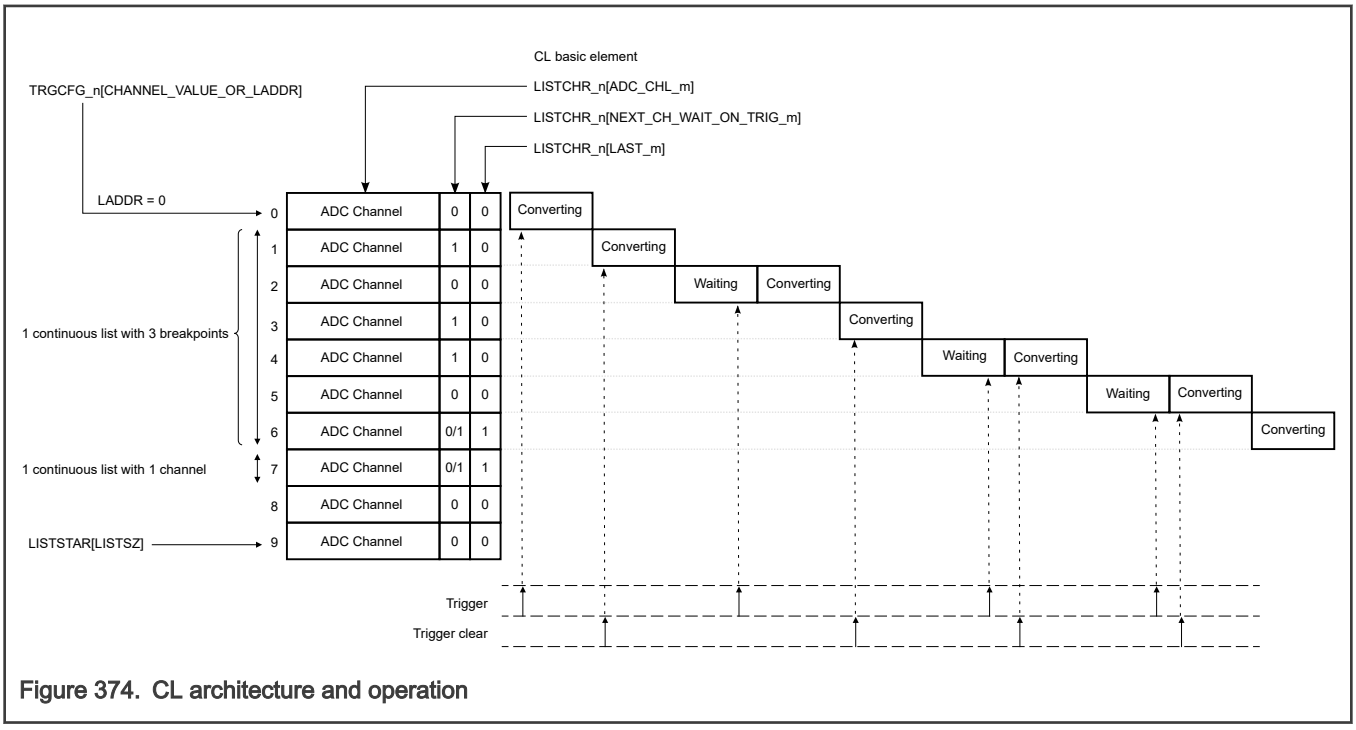

Figure 374. CL architecture and operation

64.3.2.3 CL channel rules

CL conversion obeys the following rules:

- The sequence of conversions executes until the Last Channel (LISTCHR_*n*[LAST_y] is 1).
- A CL conversion sequence precludes other conversions on the same ADC. If the CL is waiting (LISTCHR_*n*[NEXT_CH_WAIT_ON_TRIG_y] is 1), BCTU cannot route a non-CL conversion to that ADC (although that ADC remains available for normal and injected conversions).
- Two or more triggers for different ADCs may point to the same CL. This CL can drive parallel execution on the selected ADCs.
- If the Channel or CL Address (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]) does not point to a valid list address, BCTU uses address 0 by default.
- When the CL pointer reaches the last available list address (LISTSTAR[LISTSZ] minus 1), the pointer wraps to list address 0.
- You can select more than one ADC per trigger using the ADC Select n (TRGCFG_x[ADC_SELn]) fields, but selecting more than one ADC is valid only for multiple parallel CL operation. If you select more than one ADC for a single-conversion trigger, BCTU ignores the trigger.

64.3.3 ADC conversion results access

64.3.3.1 Overview

The value of DATA_DEST determines access to ADC results.

- DATA_DEST = 000: ADC results are available in the ADC data registers.
- DATA_DEST = 001: ADC results are available in FIFO 1 Result Data (FIFO Result Data (FIFO1DR - FIFO2DR)). See Route conversion data to FIFO.
- DATA_DEST = 010: ADC results are available in FIFO 2 Result Data (FIFO Result Data (FIFO1DR - FIFO2DR)). See Route conversion data to FIFO.

You can access ADC results using flags and interrupt requests (see Access on interrupt request) or DMA (see Access on DMA request). Interrupt requests are based on Module Status (MSR) flags. ADC*n*DR provides the following information, with one register used for each ADC:

- The conversion results
- The channel that was used for the conversion
- The trigger input that initiated the conversion
- Whether a CL element generated the conversion
- Whether the data was the last conversion of a CL

64.3.3.2 Access on interrupt request

If interrupts are enabled for ADC*n* Result Data (MCR[IEN*n*] is 1) and DMAs are disabled for ADC*n* Result Data (MCR[DMA*n*] is 0), BCTU generates an interrupt request for each available conversion data in ADC*n*DR. Because BCTU executes conversions on different ADCs in parallel, conversion results may be available on multiple ADCs at the same time. New Data (MSR[NDATAn] is 1) indicates that new conversion data is available in the corresponding ADC Data Result (ADC*n*DR). To clear the New Data flag, write 1 to MSR[NDATAn_CLR].

64.3.3.3 Access on DMA request

If you enable DMA requests (MCR[DMA*n*]):

- You must select one channel for DMA per ADC.
- New conversion result data (ADC*n*DR) generates a DMA request.

- The DMA controller deasserts the DMA request and writes 1 to MSR[NDATAn_CLR] to clear the flag.

When an ADC generates new data (MSR[NDATAn]), BCTU processes the DMA request. See Clear a DMA request.

64.3.3.4 Clear an interrupt request

BCTU clears an interrupt request when:

- The number of valid entries is less than or equal to the FIFOn watermark level (FIFOWM[WM_FIFO*n*]).
- You write 1 to FIFO watermark interrupt status (FIFOERR[WM_INT_FIFO*n*]).

64.3.3.5 Clear a DMA request

BCTU clears a DMA request when:

- The number of valid entries is less than or equal to the FIFOn watermark level (FIFOWM[WM_FIFO*n*]).
- The DMA controller sends acknowledgment to BCTU.

64.3.3.6 Clear an error-generated interrupt request

Clear an interrupt generated because of an error condition by writing 1 to the appropriate error flag:

- FIFOERR[OVR_ERR_FIFO1]
- FIFOERR[UNDR_ERR_FIFO1]
- FIFOERR[OVR_ERR_FIFO2]
- FIFOERR[UNDR_ERR_FIFO2]

64.3.3.7 Conversion data overrun

If new ADC conversion data becomes available before you read the previous data (ADC*n*DR), then BCTU indicates a data overrun (MSR[DATAOVRn] is 1).

If you enable interrupts for the ADC (MCR[IEN*n*]), a data overrun also generates an interrupt request, regardless of the DMA request configuration.

To clear a data overrun (MSR[DATAOVRn]), write 1 to data overrun clear (MSR[DATAOVRn_CLR]). See Clear an error-generated interrupt request.

64.3.3.8 Route conversion data to FIFO

BCTU allows you to route multiple ADC conversion results to one of 2 internal data FIFOs. Any trigger source can route results to an available FIFO based on the trigger index. Each FIFO has a dedicated counter (FIFOCNTR[CNTR_FIFO*n*]) to indicate the number of entries in the FIFO.

Each FIFO also has its own result data register (FIFO*n*DR) that contains the following information about the last conversion result routed to the FIFO.

- ADC result data
- Trigger source index
- ADC number
- ADC channel number

64.3.3.9 Read ADC result from FIFO

Each FIFO has DMA and interrupt interfaces. The DMA interface reads data. The interrupt interface indicates watermark and error conditions:

- An overrun error (FIFOERR[OVR_ERR_FIFO*n*]) occurs when you attempt to write data to an already full FIFO.
- An underrun error (FIFOERR[UNDR_ERR_FIFO*n*]) occurs when you attempt to read data from an empty FIFO.
- BCTU asserts a watermark interrupt request if the number of valid FIFO entries exceeds the watermark level (FIFOWM[WM_FIFO*n*]).

You can read a FIFO:

- by enabling DMA requests (FIFOCR[DMA_EN_FIFO*n*])
- by polling the FIFO full status (FIFOSR[FULL_FIFO*n*])

See Configuration of DMA and interrupt behavior.

64.3.3.10 Configuration of DMA and interrupt behavior

Table 423. Configuration of DMA and interrupt behavior

FIFOCR[DMA_EN_FIFO*n*]	FIFOCR[IEN_FIFO*n*]	Condition
0	0	No DMA request; no interrupt request
0	1	Interrupt request when FIFO exceeds watermark level; interrupt request on error
1	0	DMA request when FIFO exceeds watermark level
1	1	DMA request when FIFO exceeds watermark level; interrupt request on error

64.3.4 Multiple parallel conversions (MPC)

64.3.4.1 Overview

The MPC mechanism allows you to execute a series of simultaneous ADC conversions by selecting more than one ADC for any CL-configured trigger.

64.3.4.2 Configure MPC

To configure a CL to perform MPC:

1. Select CL for the trigger resolution (write 1 to TRGCFG_*m*[TRS]).
2. Select more than one ADC for the trigger (TRGCFG_*m*[ADC_SEL*n*]).
3. Specify the CL address for the first CL element (TRGCFG_*m*[CHANNEL_VALUE_OR_LADDR]).

64.3.4.3 CL address selection for MPC

When the trigger input for the CL asserts, BCTU uses the channel or list address (CHANNEL_VALUE_OR_LADDR) as an index into the CL for the lowest numbered ADC selected (ADC_SEL*n*), and each subsequent element of the CL for each remaining selected ADC. The set of selected ADC channels perform their conversions in parallel. When that set of conversions is complete, the next set of CL elements determine the next set of ADC channels to perform parallel conversions, as illustrated in:

- Example: MPC with two ADCs
- Example: MPC with three ADCs

64.3.4.4 Example: MPC with two ADCs

The following figure shows the example of MPC with two ADCs.

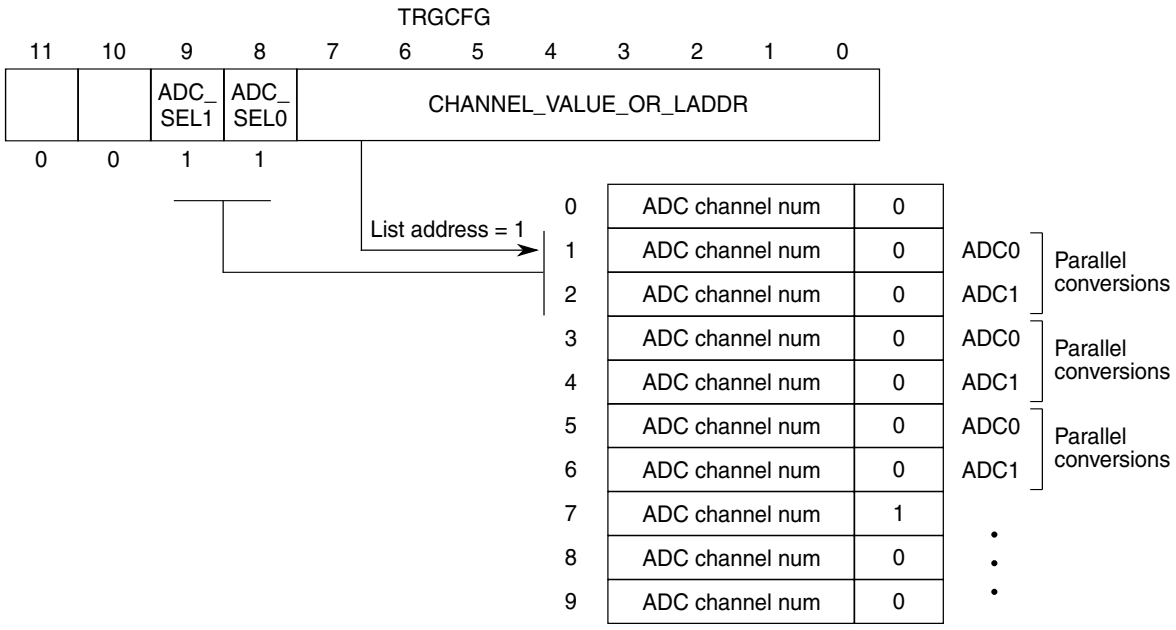

Figure 375. Example: MPC with two ADCs

64.3.4.5 Example: MPC with three ADCs

The following figure shows the example of MPC with three ADCs.

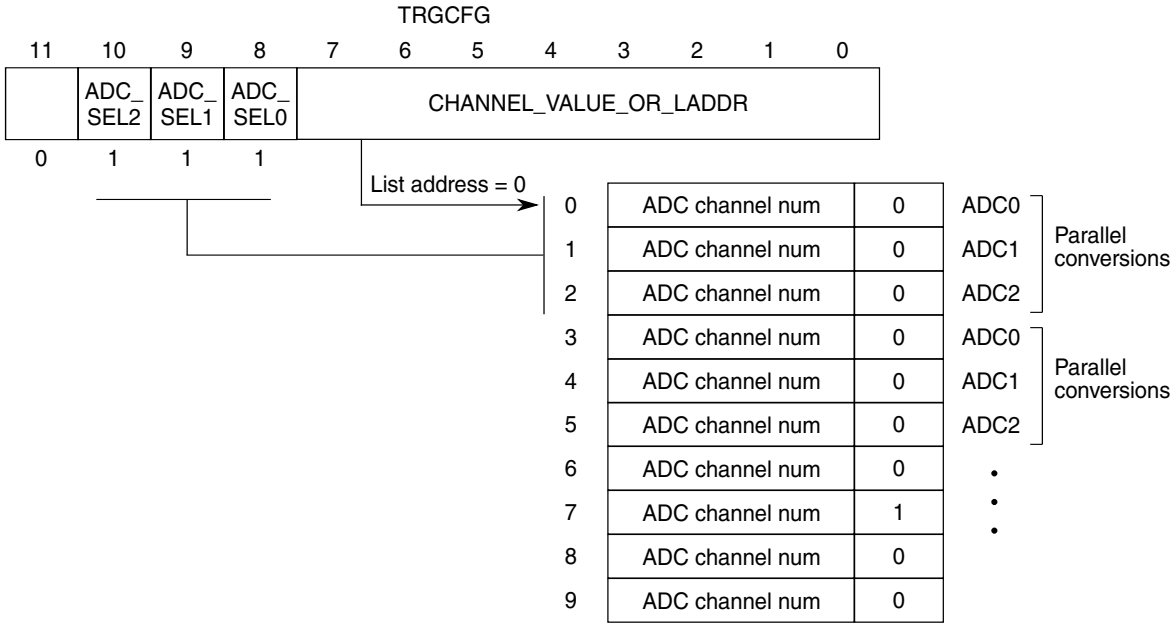

Figure 376. Example: MPC with three ADCs

64.3.4.6 MPC priority rules

MPC follows the same priority rules as for single conversions, which is based on the trigger input number: the lower the trigger, the higher the priority. However, MPC cannot start until all ADCs selected for the CL are available; that is, they are not currently

engaged in conversion. For example, if a trigger input asserts for a CL using ADC0 and ADC1, BCTU does not initiate the CL until ADC0 and ADC1 are both available.

Also, if ADC0 is available but there is a higher priority trigger for ADC1, the MPC does not start. If trigger inputs assert for two MPCs that have at least one ADC in common, the lower trigger number has higher priority. A priority conflict occurs only when separate requested CLs have at least one ADC in common. If the MPCs use different ADCs, there is no conflict and the MPCs execute at the same time.

64.3.5 Modes

64.3.5.1 Module Disable (Low Power state)

Module disable (MCR[MDIS]) stops the BCTU clock, resulting in reduced power consumption.

When you disable BCTU (write 1 to MDIS), it:

- Waits for the completion of any in-progress conversions before stopping the clock.
- Ignores all trigger inputs.
- Does not trigger any ADC conversion requests.
- Maintains any asserted trigger inputs, which you can clear if necessary.

When you re-enable BCTU (write 0 to MDIS) and global triggers are enabled (MCR[GTRGEN]), BCTU processes all active asserted trigger inputs and sends conversion requests to ADCs according to the priority scheme.

64.3.6 Clocking

This module has two clock ports.

1. ipg_clk_bctu - is the main clock of complete BCTU IP.
2. ipg_clk_s - is the gated IPG clock to be used in BCTU registers only.

64.3.7 Software reset

You can reinitialize all BCTU registers to their reset values with software reset (MCR[Software_Reset]).

Software reset does not clear any active trigger inputs, but it does put the ADC interface into the Reset state. Therefore, to avoid data incoherency, you must terminate any BCTU-triggered conversions or wait until they are complete before asserting software reset.

64.3.8 Interrupts and DMA requests

Table 424. Interrupts and DMA requests

Event	Enable interrupt	Enable DMA request	Description
Trigger Flag	MCR[TRGEN]	—	Interrupt request on assertion of trigger flag (MSR[TRGF])
ADC Data Ready	MCR[IEN*n*]	MCR[DMA*n*]	Interrupt or DMA request when ADC result data is available (ADC*n*DR)
CL Last	MCR[LIST_IEN]	—	Interrupt request when the last conversion of any CL executes
FIFO Watermark	FIFOCR[IEN_FIFO*n*]	FIFOCR[DMA_EN_FIFO*n*]	Interrupt or DMA request when the number of valid FIFO entries exceeds the FIFO

64.4 BCTU register descriptions

All BCTU registers are 32 bits wide. 8-bit write operations are allowed. The BCTU module does not include any coherence mechanism, so application software must ensure coherency.

NOTE

- You must always write 0 to reserved writable registers and fields. Read accesses of reserved registers and fields do not return meaningful data.
- For registers with write protection, if protection is active and you attempt to write to those registers, register content is unaffected and BCTU issues a transfer error.

64.4.1 BCTU memory map

BCTU base address: 4008_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Configuration (MCR)	32	RW	0000_0000h
8h	Module Status (MSR)	32	RW	0000_0000h
18h - 134h	Trigger Configuration (TRGCFG_0 - TRGCFG_71)	32	RW	0000_0000h
228h	Write Protection (WRPROT)	32	RW	0000_0000h
22Ch	Software Trigger 1 (SFTRGR1)	32	RW	0000_0000h

64.4.2 Module Configuration (MCR)

Offset

Register	Offset
MCR	0h

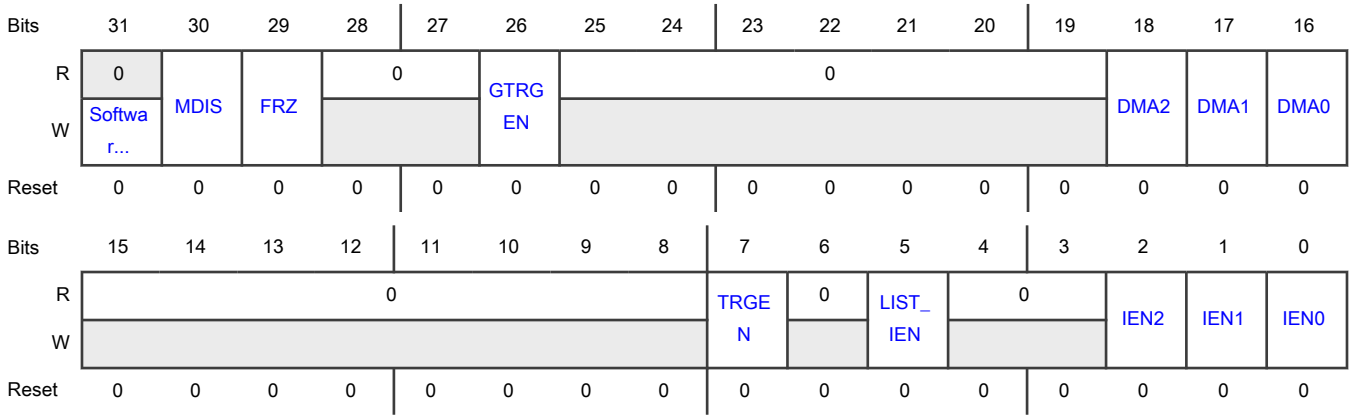
Function

Configures the following aspects of BCTU behavior:

- Low power
- Debug
- Trigger control
- DMA control
- Interrupt control

Access: User read/write

Diagram



Fields

Field	Function
31 Software_Reset	Software Reset Asserts soft reset, which initializes all BCTU registers and internal state machines to their reset values. 0b - Deasserts 1b - Asserts
30 MDIS	Module Disable Disables BCTU by putting it in Low Power state (see Module Disable (Low Power state)). 0b - Enable (normal operation) 1b - Disable (low-power operation)
29 FRZ	Debug Freeze Disables all hardware trigger inputs but leaves the software trigger enabled. Debug Freeze isolates BCTU from external triggers and allows you to manually trigger a conversion and read the conversion result. 0b - Disables 1b - Enables

Table continues on the next page...

Table continued from the previous page...

Field	Function
28-27 —	Reserved
26 GTRGEN	Global Trigger Enable Enables all individually enabled trigger inputs at the same time. For any given input trigger to be active, you must both enable the individual trigger (TRGCFG_*n*[TRIGEN]) and Global Trigger Enable. See Configure all triggers. 0b - Disable 1b - Enable
25-19 —	Reserved
18-16 DMAn	Enable ADCnDR DMA Enables DMA operation when new data is available in ADC*n*DR. 0b - Disable 1b - Enable
15-8 —	Reserved
7 TRGEN	Trigger Interrupt Request Enable Enables an interrupt request on a Trigger Flag (MSR[TRGF]). 0b - Disable 1b - Enable
6 —	Reserved
5 LIST_IEN	CL Interrupt Enable Enables an interrupt request for the last conversion in a CL (both ADC*n*DR[LIST] and ADC*n*DR[LAST] are 1). 0b - Disable 1b - Enable
4-3 —	Reserved
2-0 IENn	Interrupt Enable For ADCnDR

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables an interrupt request when BCTU writes a new conversion result to ADC Data (ADC*n*DR). Also enables an interrupt request on an overrun in ADC*n*DR, which indicates the previous data has been overwritten by a new conversion result. See also MSR[NDATA*n*] and MSR[DATAOVR*n*]]. Enabling ADC*n*DR DMA (DMA*n* field) disables the interrupt for new data in ADC*n*DR, but the interrupt for ADC*n*DR data overrun remains enabled. 0b - Disable 1b - Enable

64.4.3 Module Status (MSR)

Offset

Register	Offset
MSR	8h

Function

Indicates the status of various BCTU functions, including:

- Whether conversion data is available for each ADC
- CL operation, such as the last conversion command executed in a CL
- Whether BCTU triggered any of the ADCs

All flag fields become 0 upon assertion of a low-power (software) or clock-stop (hardware) request. You can turn off individual flags by writing 1 to the field.

Access: User read/write

64.4.4 Trigger Configuration (TRGCFG_0 - TRGCFG_71)

Offset

For a = 0 to 71:

Register	Offset
TRGCFG_a	18h + (a × 4h)

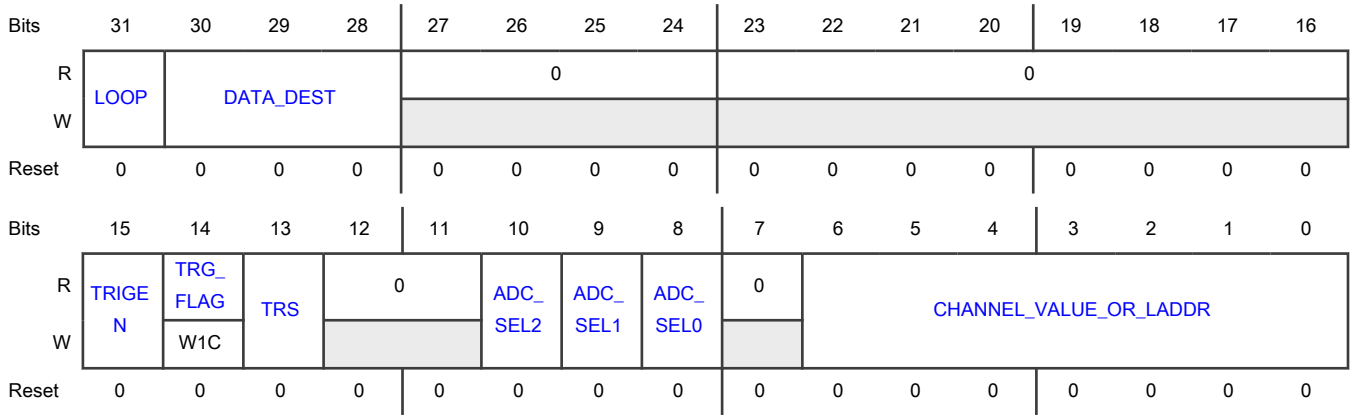
Function

Configures the corresponding trigger:

- Specifies the target ADC and ADC channel to use for conversion.
- Specifies whether to use a CL or a single ADC conversion command.

Access: User read/write

Diagram



Fields

Field	Function
31 LOOP	Loop Specifies that the current trigger executes in a loop; that is, the triggered conversion repeats until you disable Loop. Each loop-triggered conversion wins the priority evaluation among all pending triggers, and executes only if it is the highest-priority triggered conversion at the moment the conversion starts. 0b - Disable 1b - Enable
30-28 DATA_DEST	Data Destination Specifies the destination for storing the conversion results. You can route each ADC's conversion result to either of the following: • ADC-specific data registers • One of the available FIFOs BCTU routes conversion results to different destinations based on the trigger index that requested the conversion. You cannot duplicate the same data in more than one destination. 000b - ADC-specific data registers 001b - FIFO1 010b - FIFO2 011b - Reserved All other values are reserved.
27-24 —	Reserved
23-16 —	Reserved
15	Trigger Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TRIGEN	Enables hardware input triggers to initiate ADC conversions. This field does not affect software triggers. 0b - Disable 1b - Enable
14 TRG_FLAG	Trigger Flag Indicates the trigger input is asserted and an ADC conversion is in progress. When the conversion completes, BCTU changes this field to 0. Writing 1 to this field causes the input trigger event to clear when the in-progress conversion completes, and prevents this trigger from initiating a new ADC conversion until the input trigger is asserted again. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No ongoing ADC conversion initiated 1b - Ongoing ADC conversion initiated When writing 0b - No action 1b - Changes to 0
13 TRS	Trigger Resolution Selects single conversion or CL conversions. 0b - Single conversion 1b - CL conversions
12-11 —	Reserved
10-8 ADC_SELn	ADC Select n Selects ADC *n* for conversion. 0b - Deselects 1b - Selects
7 —	Reserved
6-0 CHANNEL_VALUE_OR_LADDR	Channel or CL Address Depending on the value of TRS: • 0: Specifies the ADC channel for conversion • 1: Specifies the address of the first CL position to execute

64.4.5 Write Protection (WRPROT)

Offset

Register	Offset
WRPROT	228h

Function

Enables write protection at reset exit. To allow writes to protected registers, you must write a special code into PROTEC_CODE. There are two codes to remove protection: one that permanently disables the protection; one that disables protection during one write cycle to a protected register, after which the protection code returns to the initial (protected) value of 0000b.

Access: User read/write

Field	Function
31-4 —	Reserved
3-0 PROTEC_CODE	Protection Code Controls the protection of write-protected registers. **NOTE** You can write this field only in Normal mode (MCR[MDIS] is 0). 0000b - Enable protection 1001b - Disable protection for one write cycle 1010b - Disable protection permanently

64.4.6 Software Trigger 1 (SFTRGR1)

Offset

Register	Offset
SFTRGR1	22Ch

Function

Allows you to trigger conversions on the associated triggers.

To use a software trigger, you must first disable the corresponding hardware trigger (TRGCFG_x[TRIGEN]).

BCTU writes 0 to a software trigger field on completion of the triggered conversion.

Access: User read/write; this register is write protected by Write Protection (WRPROT). If protection is enabled, writes to this register generate a transfer error and do not modify its content.

64.4.7 Software Trigger 2 (SFTRGR2)

Offset

Register	Offset
SFTRGR2	230h

Function

Allows you to trigger conversions on the associated triggers.

To use a software trigger, you must first disable the corresponding hardware trigger (TRGCFG_*n*[TRIGEN]).

BCTU writes 0 to a software trigger field on completion of the triggered conversion.

Access: User read/write; this register is write protected by Write Protection (WRPROT). If protection is enabled, writes to this register generate a transfer error and do not modify its content.

64.4.9 ADCn Result Data (ADC0DR - ADC2DR)

Offset

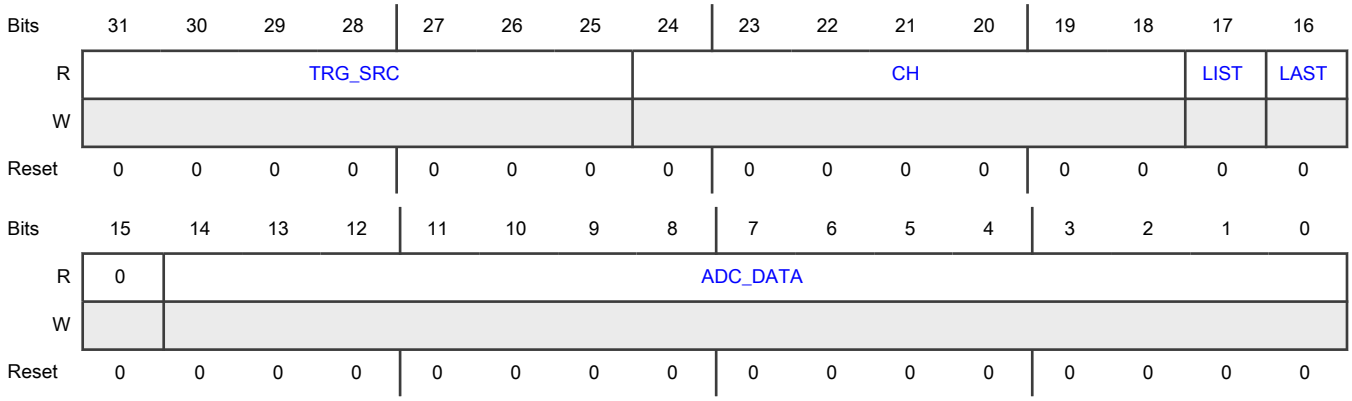
Register	Offset
ADC0DR	23Ch
ADC1DR	240h
ADC2DR	244h

Function

Provides ADC conversion result data. Also indicates the ADC channel used in that conversion, the trigger source that initiated it, and whether conversion was initiated from a CL.

Access: User read

Diagram



Fields

Field	Function
31-25 TRG_SRC	Trigger Source Contains the trigger number used to trigger the conversion.
24-18 CH	Channel Contains the ADC channel used for the conversion.
17 LIST	List Indicates whether the conversion was part of a CL or a single conversion trigger. 0b - Single conversion 1b - CL
16 LAST	Last For CL conversions, indicates this conversion result is the last conversion of the CL. 0b - Not the last conversion of a CL, or not a CL conversion 1b - Last conversion of a CL
15 —	Reserved
14-0 ADC_DATA	ADC Data Contains the data from the conversion.

64.4.10 CL Size Status (LISTSTAR)

Offset

Register	Offset
LISTSTAR	24Ch

Function

Indicates the size of the CL. Each element of the CL contains the channel number used in one conversion.

Access: User read

7-0 LISTSZ	CL Size Indicates the size of the CL in number of elements.

64.4.11 CL Channel Address (LISTCHR_0 - LISTCHR_15)

Offset

For m = 0 to 15:

Register	Offset
LISTCHR_m	250h + (m × 4h)

Function

Configures these attributes for two CL elements:

- ADC channel number to use for conversion
- Whether the element is the last element of a CL

Access: User read/write

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

6-0 ADC_CHL_y_plus_1	ADC Channel Selection Plus 1 Specifies the ADC channel to use for the (*y* + 1) element of the CL, where *y* equals (2 x *m*).

64.4.12 FIFO Result Data (FIFO1DR - FIFO2DR)

Offset

Register	Offset
FIFO1DR	450h
FIFO2DR	454h

Function

Contains the ADC conversion result and information about the conversion:

- ADC channel
- Trigger source
- ADC number

Access: User read

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

64.4.15 FIFO Error/Status (FIFOERR)

Offset

Register	Offset
FIFOERR	468h

Function

Allows you to clear FIFO error and status flags. Each FIFO has its own error and status flags that can be configured to generate an interrupt. FIFO Status (FIFOSR) maintains the status of these flags. BCTU writes a 1 to these flags, and you must then clear them using FIFOERR.

Access: User read/write

Diagram

Chapter 65
Trigger MUX (TRGMUX)

65.1 Chip-specific TRGMUX information

65.1.1 TRGMUX input output configuration and instances

This chip has one instance of TRGMUX module.

The device supports the triggering scheme between peripherals. For the supported trigger sources and destination, see the TRGMUX connectivity file attached to this document.

This device has 16 pads (SIUL2) mapped from TRGMUX inputs and TRGMUX outputs are mapped to the eMIOS channels, hence two timers channels can use a single pin of the device to do input capture.

While using TRGMUX, below points need to be taken care:

- User must ensure the minimum pulse of 100 ns on SIUL2 pads when using them as trigger source on TRGMUX.
- Pulses which are visible on pads depends on the pad type. Different pad supports different frequencies. For more details on pad types and their respective bandwidth, see section "IO signal table" in "Signal Multiplexing" chapter.
- End of conversion (EOC) signals of ADC modules are mapped on TRGMUX inputs as trigger sources. The EOC signal is asserted after ADC conversion regardless whether conversion is signaled by polling flags, interrupt or DMA transfer. The signal shall not be used to start injected conversion on same ADC channel as it will overwrite current result register.
- The minimum pulse length requirement is 1.5X of destination clock, so that it gets properly sampled at the destination IP connected to TRGMUX outputs, otherwise there are chances of missing the triggers generated from source. For example, the trigger generated from PAD for ADC conversion should be kept high/low for at least 1.5X of ADC clock so that it gets sampled in ADC clock domain. To ensure this, pulse strechers have been placed before some of the hardware modules mapped on TRGMUX outputs.
- Some PADS are being shared by both ADC and TRGMUX. It is recommended that trigger initiated from such PADS should not be used to trigger a conversion on the ADC channel mapped on same PAD. Failing to do this will cause congestion on same PAD.
- Out of all the pads mapped on TRGMUX, first four pads have glitch filters. For details, see the TRGMUX connectivity file attached to this document. The trigger pulse width should honour the pulse width requirement as per Glitch Filter specifications. The same signal can be observed at output pin if the pulse width of the input data signal is more than 400ns and no output signal should be observed if the pulse width of the input data signal is less than 20ns. A signal with a pulse width that is between 20ns and 400 ns should not be applied as the behavior is not guaranteed.
- Trigger outputs are grouped peripheral-wise and have a common lock bit based on TRGMUX REGx. For instance, normal_trigger, injected_trigger and external_sync of ADC_0 are grouped onto TRGMUX_REG0 and have a common lock bit.

65.1.2 Pulse strechers in TRGMUX

TRGMUX has some hardware modules on its input side running at faster clock than some of the IPs present on output side. For instance, eMIOS reload outputs running at 160 MHz can trigger LPI2C trigger input clocked at 40 MHz, in that case there is a high chance that trigger from eMIOS will be missed. Following Pulse strechers are added for the IPs on output side of TRGMUX.

Table 425. Pulse strechers in TRGMUX

Evaluation Parameter	ADC_0/1/2 external trigger to sync the start pulse	BCTU trigger 23/47/71	FlexIO trigger input_0/1/2/3[1]	LPI2C_0 Trigger input	LPSPI_0/1/2 Trigger input	CM7_0/1/2/3 RXEV
IP expects	Synchronized single cycle pulse	Synchronized pulse	IP requirement is to have 2 cycle pulse of flexio_clk	IP requirement is to have 2 cycle pulse of lpi2c_clk	IP requirement is to have 2 cycle pulse of lpspi_clk	Single cycle pulse
Frequency	CORE_CLK	CORE_CLK	CORE_CLK	AIPS_SLOW_CLK	LPSPI_0 - PLAT_AIPS_CLK LPSPI_1/2/3 - AIPS_SLOW_CLK	CORE_CLK
Inside IP	Used as combo signal	Flopped inside IP and clear after ADC conversion completed	Synchronized inside IP	Synchronized inside IP	Synchronized inside IP	-
At SoC	Since it an ASYNC signal and IP required synchronized single cycle pulse, so a pulse stretcher is added to convert pulse from any frequency domain into a single cycle pulse of CORE_CLK	Since slow IP such as LPCMP or from PAD can also trigger BCTU and BCTU wants that trigger should clear after the ADC conversion. So a pulse stretcher is added which convert any size of pulse to a single cycle pulse of BCTU clock (CORE_CLK)	Pulse stretcher is added to convert any pulse into a two cycle pulse of FLEXIO_CLK	Pulse stretcher is added to convert any pulse into a two cycle pulse of LPI2C_CLK	Pulse stretcher is added to convert any pulse into a two cycle pulse of LPSPI_CLK	Pulse stretcher is added to convert any pulse into a single cycle pulse of CORE_CLK
Output slot at which pulse stretcher is added	2, 6, 10	24, 25, 26	64, 65, 66, 67	84	88, 92, 96	156, 157, 158[2], 159[3]

1. These pulse stretchers are available in S32K314, S32K324 and S32K344 variants only.
2. CM7_2 is applicable for S32K358/S32K348/S32K338/S32K328 only.
3. CM7_3 is applicable for S32K388/S32K389 only.

NOTE

The trigger outputs which have pulse stretcher before them, there should be atleast a gap of 5 cycle of destination clock for back to back trigger.

65.1.3 Trigger monitor

A trigger monitor is added before the TRGMUX inputs ADC12_0_EOC, ADC12_1_EOC and ADC12_2_EOC. You can configure the UDR registers in SIUL2 to select which trigger needs to propagate to the above TRGMUX inputs. By default after coming out of reset, all the enables are 0. Hence no trigger will be coming to these 3 TRGMUX inputs.

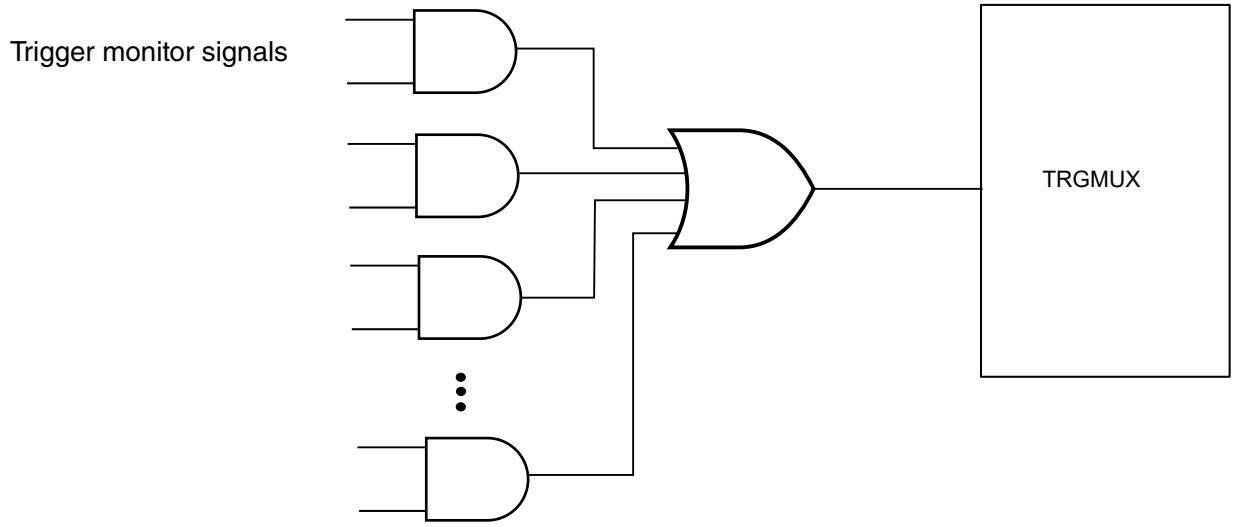

Figure 377. Trigger monitor

NOTE

Trigger monitor is not present in S32K314, S32K324 and S32K344.

65.2 Overview

TRGMUX allows you to configure the trigger inputs for various peripherals.

65.2.1 Block diagram

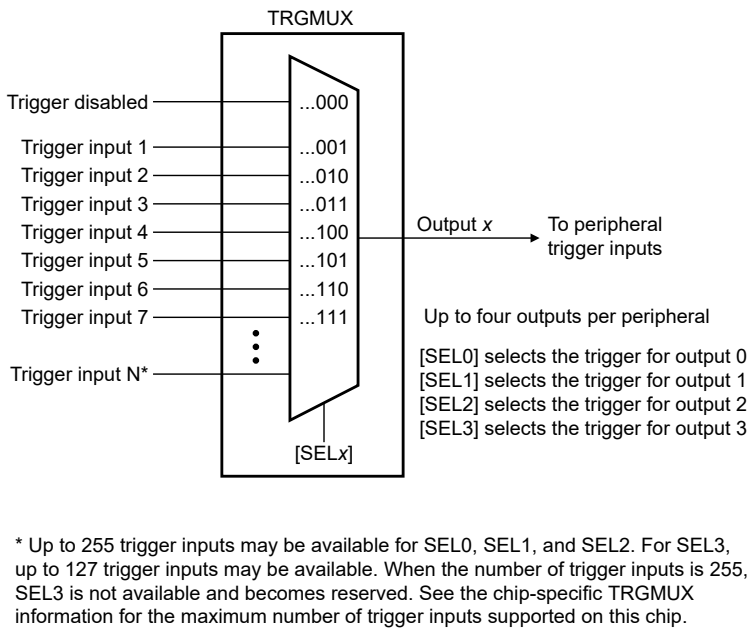

Figure 378. Block diagram

65.2.2 Features

- Configurable trigger sources for peripherals
- Dedicated TRGMUX register for each peripheral

65.3 Functional description

65.3.1 Clocking

This module has no clocking considerations.

65.3.2 Interrupts

This module has no interrupts.

65.4 External signals

This module has no external signals.

65.5 Initialization

This module does not require initialization.

65.6 TRGMUX register descriptions

65.6.1 TRGMUX memory map

You can only write to TRGMUX registers in Supervisor mode.

Table 426. Select bit fields

Chapter 66
Software Watchdog Timer (SWT)

66.1 Chip-specific SWT information

66.1.1 SWT instances and configuration

This chip supports up to four instances of SWT, one for each Cortex-M7 core.

Table 427. SWT instances

Instance	S32K388/ S32K389	S32K358	S32K348	S32K338	S32K328	S32K322/ S32K324	S32K310/S32K311/ S32K312/S32K314/ S32K342/ S32K341/S32K344
SWT_0	Yes	Yes	Yes	Yes	Yes	Yes	Yes
SWT_1	Yes	Yes	No	Yes	Yes	Yes	No
SWT_2	Yes	No	No	Yes	No	No	No
SWT_3	Yes	No	No	No	No	No	No

Table 428. SWT configuration

Instance	Core	Reset type	Clock Source	SWT_MIN_TO (100µs)	SWT_TO_RST (25ms)
SWT_0[1]	Cortex-M7_0	Functional Reset - RAM retention	SIRC (32K)	3	320h
SWT_1	Cortex-M7_1	Functional Reset - RAM retention	SIRC (32K)	3	320h
SWT_2	Cortex-M7_2	Functional Reset - RAM retention	SIRC (32K)	3	320h
SWT_3	Cortex-M7_3	Functional Reset - RAM retention	SIRC (32K)	3	320h

1. SWT_0 supports operation in STANDBY mode.

NOTE

When using SWT as a wakeup source from standby, software should ensure proper value of timeout such that SWT timeout doesn't get expired again (after wakeup till standby exit is completed). The timeout should be programmed to a value greater than the time till standby exit is complete (sum of standby exit time and the time till software disables padkeeping).

NOTE

The "Reset only the SWT" feature using SWT_RRR[RRF] is supported only when SWT reset reaction is demoted to interrupt within MC_RGM.

Protect SWT from service by non-core masters

You must program protection for the SWT registers so that only core masters can service SWT.

When an SWT timeout takes place, the logic generating a reset to the system runs off the slow internal RC oscillator (32KHz). It could therefore take the SWT almost 31.25µs to reset the system, after timeout, leaving more time for runaway code to execute. The register interface clock of SWT is running from AIPS_SLOW_CLK, see Clocking chapter for more details. The register interface clock is responsible for generating the abort for invalid access while the counter clock is responsible for generating the SWT reset request. Since there is a synchronization happening between the register interface clock and counter clock domains before generating the SWT reset request, thus the generation of the reset request can take a number of register interface clock cycles after an invalid access is done.

66.2 Overview

The Software Watchdog Timer (SWT) is a 32-bit window watchdog timer that enables the system to recover from situations such as:

- Software trapped in a loop
- A bus transaction failing to terminate

In regular operation, SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified timeout period. If this servicing action does not occur before the timer expires, SWT generates an interrupt or a hardware reset request.

You can configure SWT to generate a reset request or an interrupt on the initial timeout. SWT always generates a reset request on a second consecutive timeout.

66.2.1 Block diagram

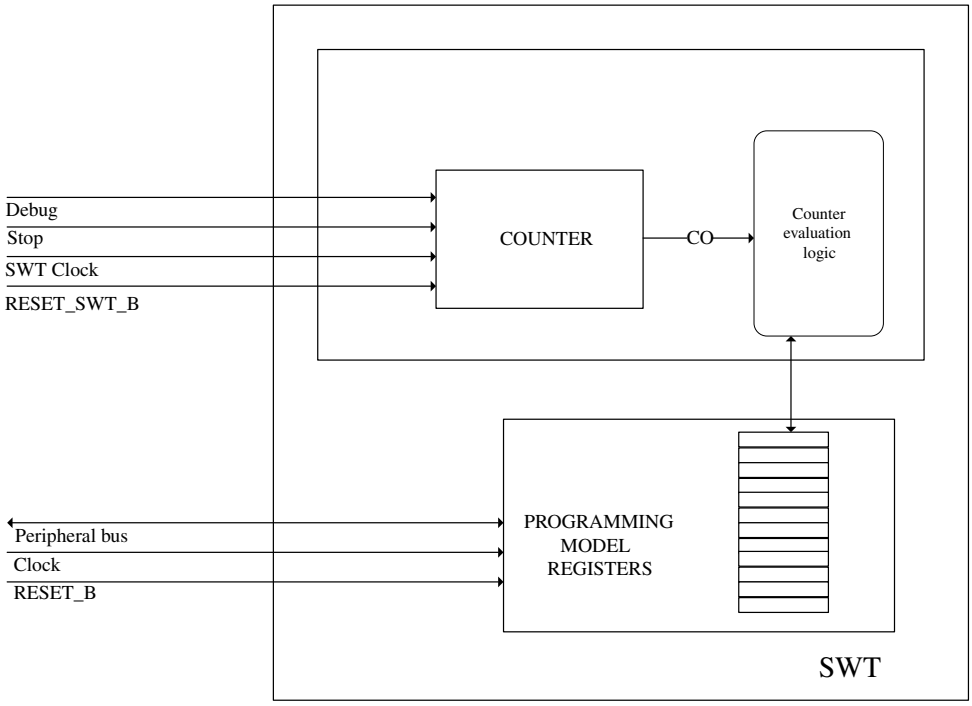

Figure 379. SWT block diagram

66.2.2 Features

SWT has the following features:

- 32-bit countdown timer
- Selection of regular or window servicing

- Selection of reset request or interrupt on an initial timeout
- Selection of fixed or keyed service sequence
- Master access protection
- Hard and soft configuration lock bits

66.3 Functional description

66.3.1 Behavior in different chip and core modes

SWT supports the core modes of operation as follows:

Core mode	SWT behavior
Normal	When SWT is enabled (CR[WEN] = 1), the SWT timer counts down continuously.
Debug	If CR[FRZ] = 1, SWT stops the timer; otherwise, the timer continues to run.

66.3.2 Register access latency

Accesses to SWT registers occur with no peripheral bus wait states. The peripheral bus bridge may add 1 or more system wait states. However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system clock cycles plus seven counter clock cycles.

66.3.3 Service key generation

SWT generates service keys with the pseudorandom key generator defined by the following equation.

$$SK_{n+1} = (17 \times SK_n + 3) \bmod 2^{16}$$

Figure 380. Pseudorandom key generator

This algorithm generates a sequence of 2^{16} different key values before repeating. In keyed service sequence mode, each time you write a valid key to SR[WSC], SWT updates SK[SK] with the next key.

For example, if the previous service key (SK[SK]) is 100h, then the next service sequence keys are 1103h followed by 2136h.

66.3.4 Clocking

The SWT has two clock domains, one for the IPS interface and the other for the counter and reset request logic. The two clocks can be asynchronous to each other and have independent resets.

See the chip-specific SWT information to find the clock source that drives the countdown timer.

66.3.5 Reset

The following table describes the SWT resets:

Table 429. SWT resets

Reset	Description
RESET_B	It is used to reset the programming model registers.
RESET_SWT_B	It is used to reset the functional domain of the SWT.

66.3.6 Interrupts

The SWT generates one interrupt:

- Timeout interrupt: it is asserted when the watchdog timer count exceeds the timeout period in the TO register.

66.3.7 Reset only the SWT

When a timeout triggers a reset request and the application does not require a system reset, you can make the SWT instance reset itself rather than the whole system.

To make a timeout reset request trigger only an SWT reset (rather than the whole system), write 1 to the Reset Request Flag (RRR[RRF]).

This action causes SWT to:

- Clear the reset request.
- If an interrupt request also occurred, clear the interrupt request (IR[TIF]).
- Reset and restart the SWT.

For systems with multiple SWT instances, this feature allows you to reset an individual SWT instance, avoiding the widespread impact of a system reset.

66.3.8 Test SWT operation

When you disable SWT, it loads the current countdown timer into CO[CNT]. When you enable SWT, it clears this register. You can use CO[CNT] to perform a software self-test of SWT.

To test SWT operation:

1. Enable the SWT (CR[WEN] = 1).
2. Do not service SWT for a fixed period of time that is less than the timeout value.
3. Disable the SWT (CR[WEN] = 0).
4. Read the value in CO[CNT] to determine whether the internal countdown timer is working properly.

NOTE

The value shown in CO[CNT] can lag behind the actual internal timer up to six system clock cycles plus eight counter clock cycles.

66.4 External signals

This module has no external signals.

66.5 Initialization

66.5.1 Initialize the SWT

To initialize the SWT, you must do the following:

- Set the timeout period.
- Control timeout behavior. There are two options:
  - Select reset request on timeout, or
  - Select interrupt on initial timeout.

You must initialize all registers before enabling SWT (CR[WEN]). You can initialize the registers in any sequence.

66.5.1.1 Set the timeout period

When you enable SWT, it loads the greater of the specified watchdog timeout period or the minimum timeout period into an internal 32-bit countdown timer every time you perform a valid service operation.

To set the watchdog timeout period:

- Write the desired timeout period to TO[WTO].

The minimum timeout period is 3 clock cycles.

66.5.1.2 Control timeout behavior

SWT can respond to a timeout in one of two ways:

- Generate an immediate reset request on any timeout.
- Generate an interrupt and load the countdown timer on an initial timeout, then generate a reset request on a subsequent timeout.

66.5.1.2.1 Select reset request on timeout

To configure SWT to generate an immediate reset request on any timeout:

- Write 0 to CR[ITR].

66.5.1.2.2 Select interrupt on initial timeout

To configure SWT to generate an interrupt on an initial timeout:

- Write 1 to CR[ITR].

In this configuration, on the initial timeout:

- SWT loads the countdown timer with the timeout period (TO[WTO]).
- SWT indicates the interrupt with the timeout interrupt flag (IR[TIF]).
- If a second consecutive timeout occurs before writing the service sequence for the first timeout, SWT generates a reset request.

You clear the interrupt flag by writing 1 to IR[TIF].

66.5.1.3 Configure locking and unlocking

You can lock the SWT configuration with either a hard lock or a soft lock. When either lock is in effect, CR, TO, WN, and SK are read-only.

66.5.1.3.1 Enable the hard lock

To enable the hard lock:

- Write 1 to CR[HLK].

Hard lock is disabled only by a reset.

66.5.1.3.2 Enable the soft lock

To enable the soft lock:

- Write 1 to CR[SLK].

66.5.1.3.3 Unlock the soft lock

To unlock the soft lock:

1. Write C520h to SR[WSC].
2. Write D928h to SR[WSC].

This unlock sequence:

- Ignores service sequence writes.
- Recognizes the unlock sequence regardless of previous writes.
- Recognizes the unlock sequence regardless of the time between writes.
- Does not require CR[WEN] to be 1.

You can write this unlock sequence at any time.

NOTE

It is possible for a keyed service sequence to unlock soft lock. See Avoid soft unlock for the procedure to handle this situation.

66.5.1.3.4 Avoid soft unlock

When SWT operates in keyed sequence service, the sequence of service keys generated by the pseudorandom generator includes the unlock keys for soft lock. If one or more service routines use both unlock keys in the proper order, 0xC520 followed at any future time by 0xD928, SWT unlocks soft lock (CR[SLK] = 0). The unlock sequence logic ignores any service keys other than the unlock keys, so the unlock keys don't have to be inserted consecutively. If the second unlock key is also the second key of a service operation, unlock occurs before the service operation completes.

To avoid unlock:

If the service routine writes a key value of C520h to SR[WSC] as a key of the service operation, then do the following:

1. Complete the service operation.
2. Complete the unlock sequence by writing the second unlock key, D928h, to SR[WSC].
3. Reinitiate the soft lock (CR[SLK] = 1).

66.5.1.4 Select behavior on an invalid access

SWT can respond to an invalid access one of two ways:

- Generate a bus error.
- Generate a bus error and, if SWT is enabled, a reset request.

To select how SWT responds to an invalid access:

- Write the appropriate value to CR[RIA].

66.5.2 Initiate service operations

When enabled, SWT requires periodic execution of a servicing operation.

SWT can operate in one of the following service sequence modes:

- Fixed service sequence
- Keyed service sequence

66.5.2.1 Initiate a fixed service sequence

To initiate the fixed service sequence:

1. Select the fixed servicing mode (write 00b to CR[SMD]).
2. Write A602h to SR[WSC].

3. Write B480h to SR[WSC].

There is no timing requirement between the two writes. The service sequence logic ignores unlock-sequence writes.

66.5.2.2 Initiate a keyed service sequence

To initiate the keyed service sequence:

1. Select the keyed servicing mode (write 01b to CR[SMD]).
2. Read the initial service key from SK[SK].
3. Calculate the next service key using the provided equation.
4. Write that service key to SR[WSC].
5. Repeat steps 2 through 4 one time.

See Service key generation for information about service keys.

66.5.2.3 Select window service mode

In window service mode, you must write the service sequence only when the watchdog timer is less than the window start value (WN[WST]). If you write the service sequence outside of this window, the access is invalid and generates a bus error or reset request depending on the Reset on Invalid Access setting (CR[RIA]).

For example, if the timeout period is 5000 and the window start value is 1000, you must write the service sequence during the last 20% of the timeout period.

Synchronization logic in SWT causes a slight delay in the opening of the window. This delay can be up to three system clock cycles plus four counter clock cycles.

To select window service mode:

- Write 1 to (CR[WND]).

66.6 SWT register descriptions

The SWT programming model allows only 32-bit (word) accesses.

Any of the following attempted accesses are invalid:

- Non-32-bit accesses
- Writes to read-only registers
- Writes of incorrect values to SR when SWT is enabled
- Accesses to reserved addresses
- Accesses by masters without permission

You control how SWT responds to an invalid access with CR[RIA].

Chapter 67
System Timer Module (STM)

67.1 Chip-specific STM information

67.1.1 STM instances and configuration

This chip has up to four instances of STM, one for each Cortex-M7 core. The STM counter increments at the STM module clock frequency divided by a pre-scaled value.

Table 430. STM instances

Instance	S32K388/ S32K389	S32K358/ S32K348/ S32K338/ S32K328	S32K322/S32K342/S32K341/S32K314/ S32K324/S32K344	S32K310/S32K311/S32K312
STM_0	Yes	Yes	Yes	Yes
STM_1	Yes	Yes	Yes	No
STM_2	Yes	Yes	No	No
STM_3	Yes	No	No	No

Table 431. STM configuration

Instance	Description	Number of Channels	Number of Registers (32-bit)
STM_0	Intended for Cortex-M7_0 core	4	14
STM_1	Intended for Cortex-M7_1 core	4	14
STM_2	Intended for Cortex-M7_2 core	4	14
STM_3	Intended for Cortex-M7_3 core	4	14

67.2 Overview

STM supports commonly required system and application software timing functions. STM includes a 32-bit count-up timer and four 32-bit compare channels with a separate interrupt source for each channel. The timer is driven by the STM module clock divided by an 8-bit prescale value (1 to 256).

67.2.1 Block diagram

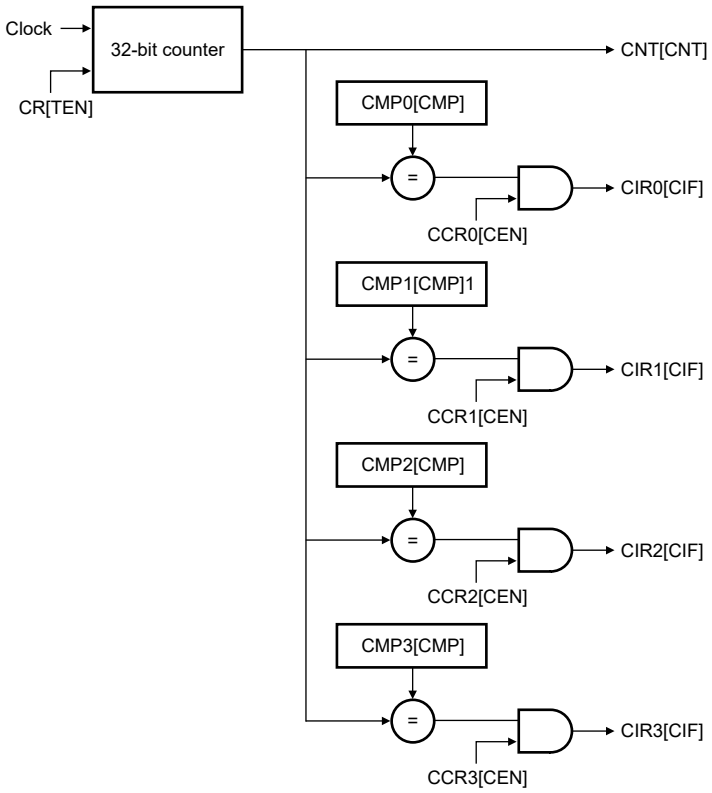

Figure 381. Block diagram

67.2.2 Features

STM has the following features:

- One 32-bit count-up timer with an 8-bit prescaler
- Four 32-bit compare channels
- An independent interrupt source for each channel
- Ability to stop the timer in Debug mode

67.3 Functional description

67.3.1 Count-up timer

STM has one 32-bit count-up timer that serves as the time base for four compare channels. When enabled, the counter increments at the module clock frequency divided by a prescaler value in the range from 1 to 256. When enabled in Normal mode, the timer increments continuously. The counter rolls over at FFFF_FFFFh to 0000_0000h with no restrictions at this boundary.

67.3.2 Compare channels

STM has four identical compare channels. Each channel includes a channel control register (CCR*n*), a channel interrupt register (CCR*n*), and a channel compare register (CMP*n*). When the channel is enabled and its channel compare value matches the timer count, STM sets the channel interrupt flag and generates an IRQ on that channel.

67.3.3 Behavior in different chip modes

STM supports the chip modes of operation as follows:

Chip mode	STM behavior
Normal	When the timer is enabled (CR[TEN] = 1), the timer counts up continuously.
Debug	If CR[FRZ] = 1, STM stops the timer. Otherwise, when the timer is enabled (CR[TEN] = 1), the timer counts up continuously.

67.3.4 Clocking

This module has no clocking considerations.

67.3.5 Interrupts

STM can generate a channel interrupt. For information, see:

- Compare channels
- Respond to compare channel events
- Channel Interrupt (CIR0 - CIR3)

67.4 External signals

This module has no external signals.

67.5 Initialization

This module does not require initialization.

67.6 Application information

67.6.1 Configure the timer

1. Set the initial timer count (CNT[CNT]).
2. Specify STM behavior in chip Debug mode (CNT[FRZ]).
3. Set the counter prescaler (CR[CPS]).
4. Start the timer (CR[TEN]).

67.6.2 Configure the compare channels

For each compare channel:

1. Set the channel compare value (CMP*n*[CMP]).
2. Enable the compare channel (CCR*n*[CEN]).

67.6.3 Respond to compare channel events

For each compare channel:

1. Check the channel interrupt flag (CIR*n*[CIF]).
2. If the channel interrupt flag is set, respond to the interrupt request.
3. When the channel interrupt has been handled, clear the channel interrupt flag (CIR*n*[CIF]).

67.7 STM register descriptions

The STM programming model allows only 32-bit (word) accesses. An attempted reference using a different size or to a reserved address generates a bus error termination.

67.7.1 STM memory map

STM_0 base address: 4027_4000h

STM_1 base address: 4047_4000h

67.8 Glossary

IRQ Interrupt request

Chapter 68
Periodic Interrupt Timer (PIT)

68.1 Chip-specific PIT information

68.1.1 PIT instances and configuration

This chip has up to four instances of the PIT each with 4 PIT timers/channels, each channel being 32 bits in length.

Table 432. PIT instances

Instance	S32K388/S32K389	S32K358/S32K348/ S32K338/S32K328/ S32K324/S32K344/ S32K314/S32K342/ S32K341/S32K322	S32K312	S32K311/S32K310
PIT_0	Yes	Yes	Yes	Yes
PIT_1	Yes	Yes	Yes	Yes
PIT_2	Yes	Yes	No	No
PIT_3	Yes	No	No	No

Table 433. PIT instances and features

Feature	PIT_0	PIT_1	PIT_2	PIT_3
Real time interrupt (RTI)	Yes (32-bit)[1]	No	No	No
Lifetime Timer	Yes	No	No	No
Timer chaining to create a 64-bit timer	Yes	No	No	No
Number of 32-bit timer channels	4	4	4	4
Timer value unchanged by a non-destructive reset	No	No	No	No

1. The RTI on PIT_0 supports operation in STANDBY mode

The RTI shall be possible to set the timer resolution to 1us independently to other timers. The interrupt can be generated by programming LDVAL0, LDVAL1, LDVAL2 and LDVAL3 to 48 in case of 48 MHz FIRC as system clock and 40 in case of 40 MHz system clock to generate an interrupt after 1us.

68.1.2 Input Output

All the PIT instances are capable of generating periodic triggers. PIT triggers are routed to motor control IPs such as eMIOS, LCU, BCTU, ADC etc. via TRGMUX. See the TRGMUX connectivity file attached to this document for details.

68.2 Overview

PIT includes:

- An array of timers that can be used to raise interrupts and trigger DMA channels.
- A dedicated RTI timer that runs on a separate oscillator clock and can be used for system wakeup

68.2.1 Block diagram

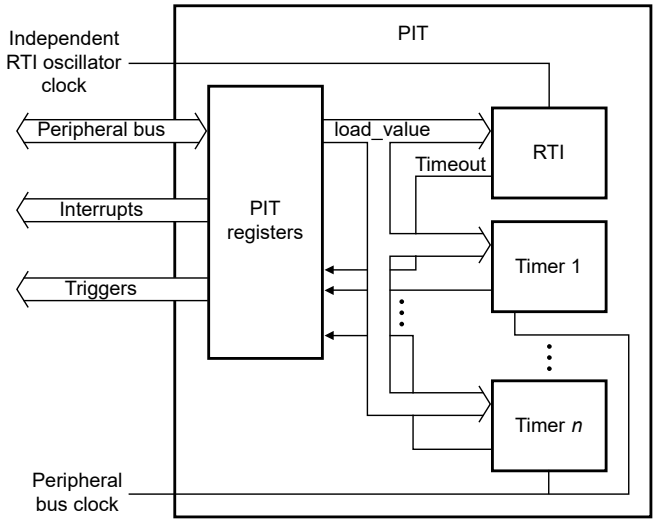

Figure 382. Block diagram

68.2.2 Features

The key features of the module are:

- 4 32-bit countdown timers
- Independent timeout periods for each timer
- Ability to chain two timers into a 64-bit lifetimer
- Ability of timers to generate interrupts
- Ability of timers to generate DMA trigger pulses
- Maskable interrupts
- One RTI countdown timer to wake up the CPU
- Option to generate the RTI even when the bus clock is off
- Power saving with a separate input clock for the RTI timer. All other timers share a common core clock.

68.3 Functional description

68.3.1 Modes of operation

Mode	Description
Run	All functional parts of the PIT operate normally.
Debug	Timers run or stop depending on the Freeze setting (MCR[FRZ]). See Debug mode.

68.3.2 Timer operation

When you enable a timer (write 1 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]), the timer counts down (one count per clock cycle) from its initial start value (LDVAL*n*[TSV] or RTI_LDVAL[TSV]). When the timer period expires (CVAL*n*[TVL] or RTI_CVAL[TVL] reaches

0), PIT sets the Timer Interrupt Flag (writes 1 to TFLG*n*[TIE] or RTI_TFLG[TIE]). It then reloads the timer start value and starts the timer counting down again.

If the timer interrupt is enabled (TCTRL*n*[TIE] or RTI_TCTRL[TIE] = 1), it generates an interrupt when it sets the Timer Interrupt Flag. The timer cannot generate a new interrupt until you clear the flag from the previous interrupt. Because clearing the RTI crosses clock domains, you should use a minimum RTI timer load value of 32.

You can read the current counter value of any timer (CVAL*n*[TVL] or RTI_CVAL[TVL]). Because the RTI timer is synchronized to the RTI clock domain, the value of the RTI counter may be several cycles old when read.

See these related topics:

- Stop and start a timer
- Change timer period
- Change timer period dynamically

NOTE

- If Freeze is enabled (MCR[FRZ] = 1) when the timer nears 0, the Debug mode command may not reach PIT before the timer expires and generates a trigger.
- If a timer is at zero when Debug mode is asserted, the interrupt trigger remains asserted until the device exits Debug mode. Clear the Timer Interrupt Flag (write 1 to TFLG*n*[TIF] or RTI_TFLG[TIF]) upon Debug exit.
- If Freeze is enabled (MCR[FRZ] = 1), sufficient time must be ensured for the IP to react.

68.3.2.1 Stop and start a timer

To restart a running timer:

1. Disable the timer (write 0 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]).
2. Enable the timer (write 1 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]).

   Enabling the timer reloads the start value and starts the timer counting down again. See Restart counter period.

68.3.2.2 Restart counter period

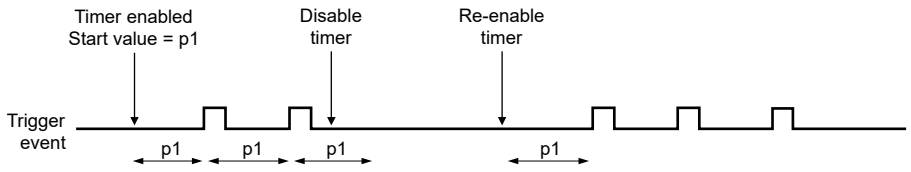

Figure 383. Restart counter period

68.3.2.3 Change timer period

To change the counter period of a running timer:

1. Disable the timer (write 0 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]).
2. Specify a new start value (LDVAL*n*[TSV] or RTI_LDVAL[TSV]).
3. Enable the timer (write 1 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]).

   Enabling the timer loads the new start value and starts the timer counting down again. See Change current timer period.

68.3.2.4 Change current timer period

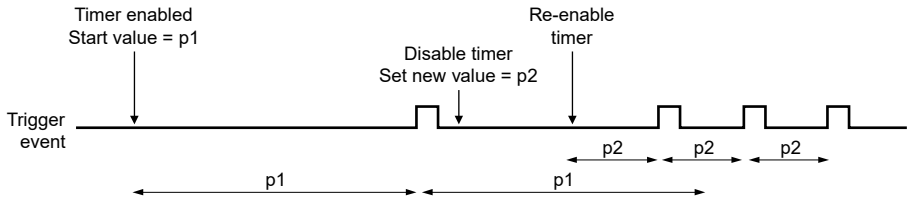

Figure 384. Change timer period dynamically timing

68.3.2.5 Change timer period dynamically

To change the counter period of a running timer:

- Specify a new start value (LDVAL*n*[TSV] or RTI_LDVAL[TSV])

  The next time the timer expires, it loads the new start value. See Dynamically setting a new timer period.

68.3.2.6 Dynamically setting a new timer period

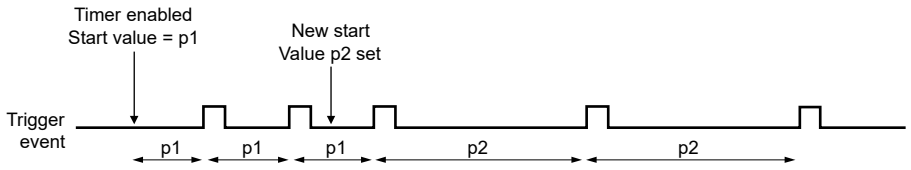

Figure 385. Dynamically setting a new timer period

68.3.3 Chained timers

PIT supports chaining two timers together to support timer periods greater than FFFFFFFFh. When a timer *n* has chain mode enabled, it decrements each time timer *n* - 1 expires. The chained timer sets its Timer Interrupt Flag when it expires (CVAL*n* = 0).

For example, assume you need to configure a timer period of 6,000,000,000 cycles. You could specify a start value of 10 for timer *n* and 599,999,999 for timer *n* - 1. With these values, the chained timer expires after timer *n* - 1 has expired ten times.

You cannot chain timer 0 or the RTI timer to another timer.

For an example configuration of a chained timer, see Example configuration using chained timers.

68.3.4 Lifetimer

PIT supports a 64-bit lifetimer. You configure the lifetimer by chaining timer 1 to timer 0 and populating the start values for both timers with the maximum value of FFFFFFFFh. You read the lifetimer in the LTMR64H and LTMR64L registers. LTMR64H returns the upper 32 bits of the lifetimer value and LMTR64L returns the lower 32 bits. When a timer 1 has chain mode enabled, it decrements each time timer 0 expires. The lifetimer expires when CVAL1 expires.

When you chain timer 1 to timer 0, timer 1 decrements every time timer 0 expires. To obtain the correct lifetimer value, read LTMR64H first and then read LTMR64L. When you read LTMR64H, it returns the value in CVAL1 (the chained timer value), and immediately latches the value from CVAL0 into LTMR64L. This latching eliminates the carryover effects of the running counter.

For an example configuration of the lifetimer, see Example configuration using the lifetimer.

68.3.5 Debug mode

If Freeze is enabled (MCR[FRZ] = 1), the timers stop if the device enters Debug mode. This freeze allows the software developer to halt the processor, investigate the current state of the system, including the PIT timer values, and then continue operation.

68.3.6 Clocking

The PIT general-purpose timers are driven by the peripheral bus clock.

The RTI timer is driven by an independent oscillator clock. This clock input continues running when the device is in Stop mode. Driving the RTI timer with an independent clock allows the RTI to trigger periodic wake-up from Stop mode.

68.3.7 Interrupts

All of the timers support interrupt generation.

You enable interrupt generation for each individual timer (TCTRL*n*[TIE]). Each interrupt is available on a separate interrupt output.

When a timer expires (CVAL*n*[TVL] = 0), it sets the Timer Interrupt Flag (TFLG*n*[TIF]) regardless of whether the interrupt is enabled. To enable generation of an interrupt when the Timer Interrupt Flag is set, write 1 to TCTRL*n*[TIE]. To clear the Timer Interrupt Flag, write 1 to it.

When the RTI timer expires (RTI_CVAL*n*[TVL] = 0), PIT sets the RTI Timer Interrupt Flag (RTI_TFLG*n*[TIF]) regardless of whether the RTI is enabled. To enable generation of an RTI when the RTI Timer Interrupt Flag is set, write 1 to TCTRL*n*[TIE]. To clear the RTI Timer Interrupt Flag, write 1 to it.

The RTI is typically used for periodic wake-up from Standby mode, but it can also be used to generate a general-purpose interrupt.

68.4 External signals

PIT has no external inputs.

68.5 Initialization

To initialize PIT:

1. For each timer *n* you plan to use:
    a. Specify the timer period (LDVAL*n*[TSV]).

       To calculate the load value for a timer:

       Start value = (timer period / clock period) - 1

    b. If you want the timer to generate an interrupt each time it expires, enable the timer interrupt (write 1 to TCTRL*n*[TIE]).
    c. If you want to use this timer as the divisor of a pair of chained timers, chain this timer to the next lower-numbered timer (write 1 to TCTRL*n*[CHN]). You cannot chain timer 0. If you want to use the lifetimer, chain timer 1 to timer 0.
    d. Enable the timer (write 1 to TCTRL*n*[TEN]).
2. If you want to use the RTI feature:
    a. Specify the RTI timer period (RTI_LDVAL*n*[TSV]).
    b. Enable the RTI timer interrupt (write 1 to RTI_TCTRL*n*[TIE]).
    c. Enable the RTI timer (write 1 to RTI_TCTRL*n*[TEN]).
3. Activate, or enable, PIT (write 0 to MCR[MDIS]).

   All enabled timers load their start values and begin counting down.

For example configurations, see Application information.

68.6 Application information

68.6.1 Example configuration for general timers

In this example configuration:

- The PIT clock frequency is 50 MHz, which equates to a clock cycle of 20 ns.
- The RTI clock frequency is 10 MHz, which equates to a clock cycle of 100 ns.
- The RTI timer needs to generate a wake-up interrupt every 500 ms.
- Timer 1 needs to generate an interrupt every 5.12 ms.
- Timer 3 needs to generate a trigger event every 30 ms.

To configure PIT for this example:

1. Disable PIT (write 1 to MCR[MDIS]).
2. Use the formula in Initialization to calculate the load value for the RTI timer:

   (500 ms/100 ns) - 1 = 4,999,999 cycles, or 004C4B3Fh.
3. Specify the RTI timer load value (write 004C4B3Fh to RTI_LDVAL[TSV]).
4. Enable the RTI (write 1 to RTI_TCTRL[TIE])
5. Enable the RTI timer (write 1 to RTI_TCTRL*n*[TEN]).
6. Use the formula in Initialization to calculate the load value for timer 1:

   (5.12 ms/20 ns) - 1 = 255,999 cycles, or 0003E7FFh.
7. Disable timer 1 (write 0 to TCTRL1[TEN]).
8. Specify the timer 1 value (write 0003E7FFh to LDVAL1[TSV]).
9. Enable the timer 1 interrupt (write 1 to TCTRL1[TIE])
10. Enable timer 1 (write 1 to TCTRL1[TEN]).
11. Calculate the load value for timer 3:

    (30 ms/20 ns) - 1 = 1,499,999 cycles, or 0016E35Fh.
12. Disable timer 3 (write 0 to TCTRL3[TEN]).
13. Specify the timer 3 value (write 0016E35Fh to LDVAL3[TSV]).
14. Enable timer 3 (write 1 to TCTRL3[TEN]).
15. Activate, or enable, PIT (write 0 to MCR[MDIS]).

NOTE

You can configure timers without first disabling PIT or the timer itself. However, if PIT is running, be aware that when a timer begins using a new start value depends on whether the timer is running or disabled when you specify the new start value. For more information, see Timer operation.

The following example code provides the described configuration:

```
// Disable PIT (see note above)
PIT_MCR = 0x02;
```

```
// RTI
PIT_RTI_LDVAL = 0x004C4B3F; // Configure RTI for 5000000 cycles
```

```
PIT_RTI_TCTRL = PIT_TIE;    // Enable RTI
PIT_RTI_TCTRL |= PIT_TEN;   // Start RTI timer
```

```
// Timer 1
PIT_LDVAL1 = 0x0003E7FF;    // Configure timer 1 for 256000 cycles
PIT_TCTRL1 = TIE;           // Enable Timer 1 interrupts
PIT_TCTRL1 |= TEN;          // Start Timer 1
```

```
// Timer 3
PIT_LDVAL3 = 0x0016E35F;    // Configure timer 3 for 1500000 cycles
PIT_TCTRL3 = TEN;           // Enable Timer 3
```

```
 // Enable PIT
 PIT_MCR = 0x00;
```

68.6.2 Example configuration using chained timers

In this example configuration:

- The PIT clock frequency is 100 MHz, which equates to a clock cycle of 10 ns.
- Timers 1 and 2 are available.
- An interrupt is needed every minute. Using the formula in Initialization, a 1 minute timer period requires:

  (60 s/10 ns) - 1 = 5,999,999,999 cycles, or 165A0BBFFh

  This value requires more than 32 bits.

To configure PIT for this example:

1. Disable PIT (write 1 to MCR[MDIS]).
2. Disable timer 1 (write 0 to TCTRL1[TEN]).
3. Disable timer 2 (write 0 to TCTRL2[TEN]).
4. Chain timer 2 to timer 1 (write 1 to TCTRL2[CHN]).
5. For the timer 2 start value, select a value that divides evenly into the desired period. For this example, we are using 10. For the timer 1 value, divide the full timer period by the selected divisor: 6,000,000,000/10 = 600,000,000.
6. Specify the timer 2 value as the selected divisor (write 00000009h to LDVAL2[TSV]).
7. Specify the timer 1 value as the quotient minus 1, or 599,999,999 (write 0x23C345FFh to LDVAL1[TSV]).
8. Enable the timer 2 interrupt (write 1 to TCTRL2[TIE])
9. Enable timer 2 (write 1 to TCTRL2[TEN]).
10. Enable timer 1 (write 1 to TCTRL1[TEN]).
11. Activate, or enable, PIT (write 0 to MCR[MDIS]).

The following example code matches the described configuration:

```
// Disable PIT
PIT_MCR = 0x02;
```

```
// Timer 2
PIT_LDVAL2 = 0x00000009; // Configure Timer 2 to the divisor (10)
PIT_TCTRL2 = TIE;        // Enable Timer 2 interrupt
PIT_TCTRL2 |= CHN;       // Chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN;       // Enable Timer 2
```

```
// Timer 1
PIT_LDVAL1 = 0x23C345FF; // Configure Timer 1 to 600,000,000 cycles
PIT_TCTRL1 = TEN;        // Enable Timer 1
```

```
 // Enable PIT
 PIT_MCR = 0x00;
```

68.6.3 Example configuration using the lifetimer

To configure the lifetimer:

1. Disable PIT (write 1 to MCR[MDIS]).
2. Disable timer 0 (write 0 to TCTRL0[TEN]).
3. Disable timer 1 (write 0 to TCTRL1[TEN]).
4. Chain timer 1 to timer 0 (write 1 to TCTRL1[CHN]).
5. Specify the maximum start value for timer 1 (write FFFFFFFFh to LDVAL1[TSV]).
6. Specify the maximum start value for timer 0 (write FFFFFFFFh to LDVAL0[TSV]).
7. Enable timer 1 (write 1 to TCTRL1[TEN]).
8. Enable timer 0 (write 1 to TCTRL0[TEN]).
9. Activate, or enable, PIT (write 0 to MCR[MDIS]).

To access the lifetimer, first read LTMR64H and then LTMR64L. For more information, see Lifetimer.

The following example code matches the described setup:

```
// Disable PIT
PIT_MCR = 0x02;
```

```
// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1
```

```
// Timer 0
```

```
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

```
// Read lifetimer
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

```
 // Enable PIT
 PIT_MCR = 0x00;
```

68.7 PIT register descriptions

This section provides a detailed description of all registers accessible in the PIT_RTI module.

- See the chip-specific PIT information for the number of PIT channels used in this MCU.
- Program RTI registers only when the RTI clock is running.

68.7.1 PIT memory map

PIT_0 base address: 400B_0000h

PIT_1 base address: 400B_4000h

PIT_2 base address: 402F_C000h

PIT_3 base address: 4030_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	PIT Module Control (MCR)	32	RW	See section
E0h	PIT Upper Lifetimer (LTMR64H)	32	R	0000_0000h
E4h	PIT Lower Lifetimer (LTMR64L)	32	R	0000_0000h
ECh	RTI Timer Load Value Sync Status (RTI_LDVAL_STAT)	32	RW	0000_0000h
F0h	RTI Timer Load Value (RTI_LDVAL)	32	RW	0000_0000h
F4h	Current RTI Timer Value (RTI_CVAL)	32	R	0000_0000h
F8h	RTI Timer Control (RTI_TCTRL)	32	RW	0000_0000h
FCh	RTI Timer Interrupt Flag (RTI_TFLG)	32	RW	0000_0000h
100h	Timer Load Value (LDVAL0)	32	RW	0000_0000h
104h	Current Timer Value (CVAL0)	32	R	0000_0000h
108h	Timer Control (TCTRL0)	32	RW	0000_0000h

68.7.2 PIT Module Control (MCR)

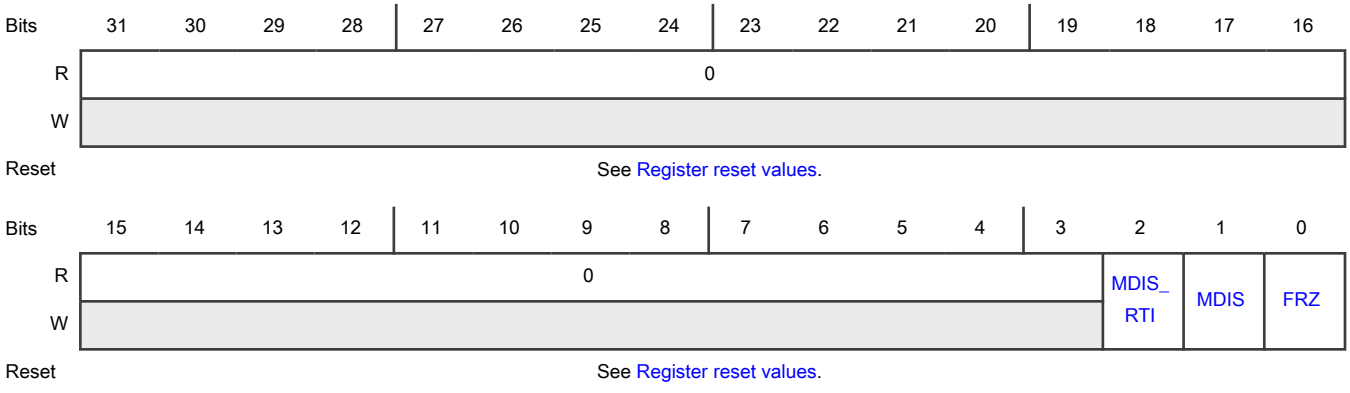
Offset

Register	Offset
MCR	0h

Function

Enables the PIT timer clocks and specifies the behavior of the timers when PIT enters Debug mode.

Diagram



Register reset values

Register	Reset value
MCR	PIT_0: 0000_0006h PIT_1–PIT_3: 0000_0002h

Fields

Field	Function
31-3 —	Reserved
2 MDIS_RTI	Module Disable for RTI Disables the RTI timer. You must write 1 to this field before setting up an RTI. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
PIT_0	MCR	—
PIT_1	—	MCR
PIT_2	—	MCR
PIT_3	—	MCR

	0b - Enables 1b - Disables
1 MDIS	Module Disable for PIT Disables the standard timers. This field does not affect the RTI timer. You must disable the clock (write 1 to MDIS) before configuring PIT. After configuration, you must enable the clock (write 0 to MDIS). 0b - Enables 1b - Disables
0 FRZ	Freeze Stops the timers when the device enters Debug mode. 0b - Timers run in Debug mode 1b - Timers stop in Debug mode

68.7.3 PIT Upper Lifetimer (LTMR64H)

Offset

Register	Offset
LTMR64H	E0h

Function

Combined with LTMR64L, provides a 64-bit lifetimer constructed from the values in two chained PIT timers.

For more information, see Lifetimer.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	LTMR64H	—
PIT_1	—	LTMR64H
PIT_2	—	LTMR64H
PIT_3	—	LTMR64H

Diagram

R	LTH															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 LTH	Lifetimer Value Indicates the timer value of timer 1. This value is the upper 32 bits of the 64-bit lifetimer value. When you read this register at t1, the value of timer 0 at t1 is latched into LTMR64L.

68.7.4 PIT Lower Lifetimer (LTMR64L)

Offset

Register	Offset
LTMR64L	E4h

Function

Combined with LTMR64H, provides a 64-bit lifetimer.

For more information, see Lifetimer.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	LTMR64L	—
PIT_1	—	LTMR64L
PIT_2	—	LTMR64L
PIT_3	—	LTMR64L

Diagram

R	LTL															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 LTL	Lifetimer Value Indicates the timer value of timer 0 at the moment LTMR64H was last read. This value is the lower 32 bits of the 64-bit lifetimer value. This field updates only when LTMR64H is read.

68.7.5 RTI Timer Load Value Sync Status (RTI_LDVAL_STAT)

Offset

Register	Offset
RTI_LDVAL_STAT	ECh

Function

Indicates whether the RTI timer start value has been loaded (RTI_LDVAL). This status is necessary because it takes several cycles for the RTI start value to synchronize into the RTI clock domain.

NOTE

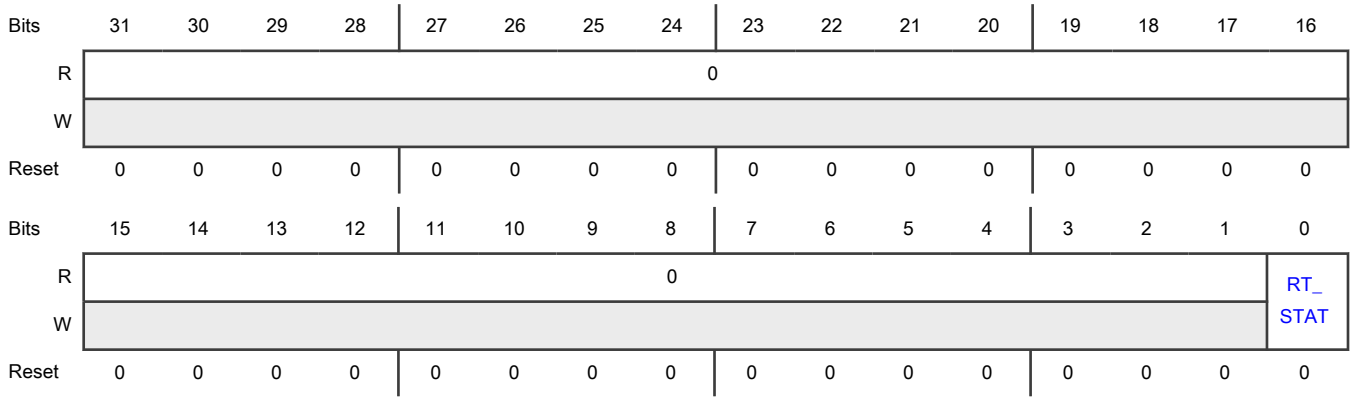
In the case of dynamic loading (Figure 385) of the RTI timer, this status may be unreliable .

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_LDVAL_STAT	—
PIT_1	—	RTI_LDVAL_STAT
PIT_2	—	RTI_LDVAL_STAT
PIT_3	—	RTI_LDVAL_STAT

Diagram



Fields

Field	Function
31-1 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 RT_STAT	Sync Status Indicates whether the RTI start value is loaded. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not loaded 1b - Loaded When writing 0b - Clears status 1b - Clears status

68.7.6 RTI Timer Load Value (RTI_LDVAL)

Offset

Register	Offset
RTI_LDVAL	F0h

Function

Specifies the length of the RTI timeout period in clock cycles.

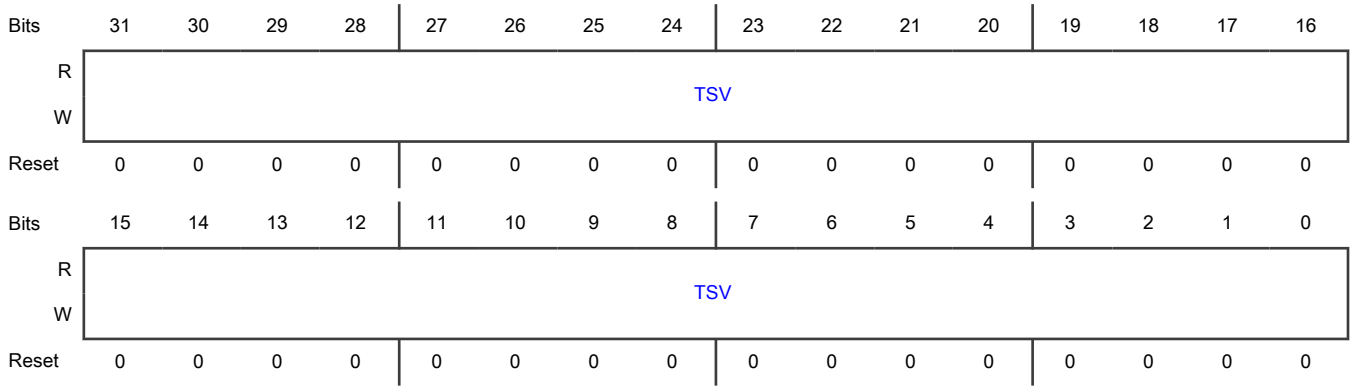
It takes several cycles for this value to synchronize into the RTI clock domain.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_LDVAL	—
PIT_1	—	RTI_LDVAL
PIT_2	—	RTI_LDVAL
PIT_3	—	RTI_LDVAL

Diagram



Fields

Field	Function
31-0 TSV	Timer Start Value Specifies the starting RTI timer value. The timer counts down until it reaches 0, then sets the interrupt flag and reloads this value. When you write a new value to this register, the timer does not restart with the new value until the current timing period expires. To terminate the current period and start a new period with the new value, you must disable the timer (write 0 to RTI_TCTRL*n*[TEN]) and then enable it again (write 1 to RTI_TCTRL*n*[TEN]). **NOTE** Because it may take several cycles to clear the RTI interrupt, setting the value to something less than 32 cycles may result in a lost interrupt.

68.7.7 Current RTI Timer Value (RTI_CVAL)

Offset

Register	Offset
RTI_CVAL	F4h

Function

Indicates the current RTI timer value. Because this timer might be driven from a different clock domain from the other timers, the value may be several cycles old.

NOTE

Each module instance supports a different number of registers.

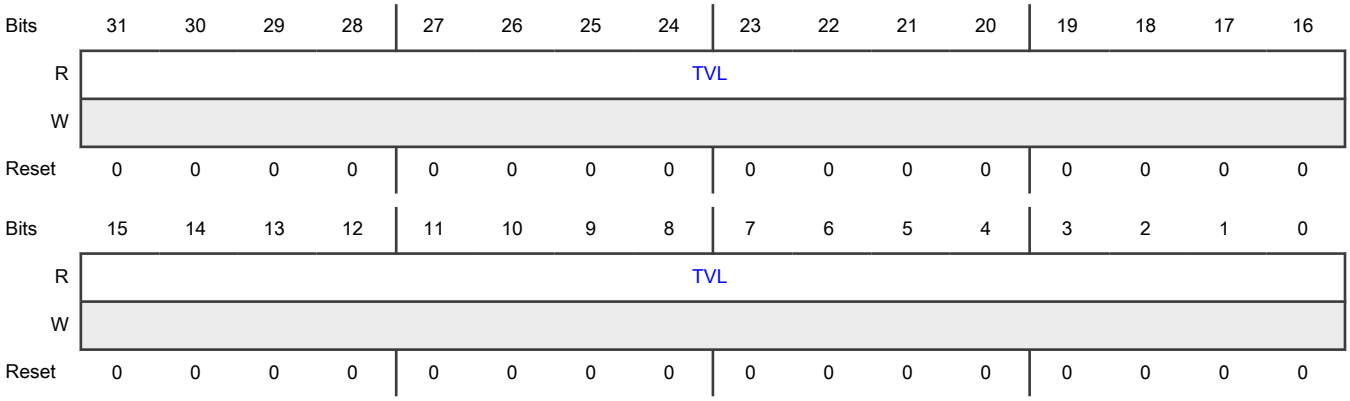
Instance	Register supported	Register not supported
PIT_0	RTI_CVAL	—
PIT_1	—	RTI_CVAL

Table continues on the next page...

Table continued from the previous page...

Instance	Register supported	Register not supported
PIT_2	—	RTI_CVAL
PIT_3	—	RTI_CVAL

Diagram



Fields

Field	Function
31-0 TVL	Current Timer Value Indicates the current RTI timer value. **NOTE** • If the timer is disabled (RTI_TCTRL*n*[TEN] = 0), this value has no meaning. • If PIT is frozen in Debug mode (MCR[FRZ] = 1), timer values are frozen when the device is in Debug mode.

68.7.8 RTI Timer Control (RTI_TCTRL)

Offset

Register	Offset
RTI_TCTRL	F8h

Function

Controls RTI timer behavior.

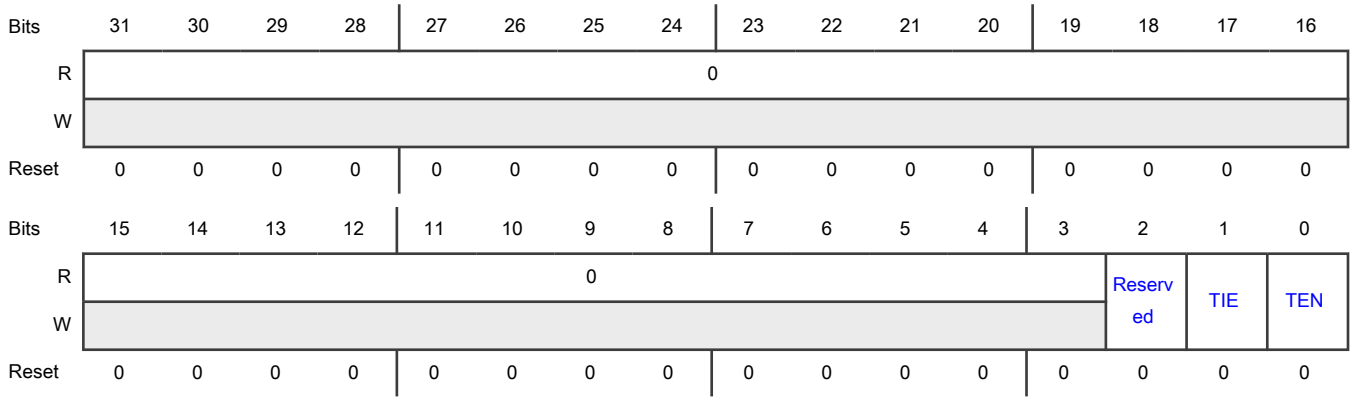
The RTI may take several RTI clock cycles to enable or update. Therefore, you must wait for at least three RTI clock cycles after RTI configuration before relying on the RTI timer.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_TCTRL	—
PIT_1	—	RTI_TCTRL
PIT_2	—	RTI_TCTRL
PIT_3	—	RTI_TCTRL

Diagram



Fields

Field	Function
31-3 —	Reserved
2 —	Reserved
1 TIE	Timer Interrupt Enable Enables the RTI timer interrupt. If the interrupt is enabled, when an interrupt is pending or the Timer Interrupt Flag is set (RTI_TFLG*n*[TIF] = 1), PIT generates an interrupt. To avoid an interrupt when you first enable the interrupt, clear the Timer Interrupt Flag (write 1 to RTI_TFLG*n*[TIF]) before you enable the interrupt. 0b - Disables 1b - Enables
0 TEN	Timer Enable Bit Enables the RTI timer.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disables 1b - Enables. The RTI timer begins counting down.

68.7.9 RTI Timer Interrupt Flag (RTI_TFLG)

Offset

Register	Offset
RTI_TFLG	FCh

Function

Indicates the RTI timer has expired.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_TFLG	—
PIT_1	—	RTI_TFLG
PIT_2	—	RTI_TFLG
PIT_3	—	RTI_TFLG

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0															TIF
W																W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-1 —	Reserved
0 TIF	Timer Interrupt Flag Indicates the RTI timer period has expired (CVAL*n*[TVL] = 0). If interrupts are enabled (RTI_TCTRL*n*[TIE] = 1), TIF triggers an interrupt request. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Timer still counting down 1b - Timer has expired When writing 0b - No effect 1b - Clears the flag

68.7.10 Timer Load Value (LDVAL0 - LDVAL3)

Offset

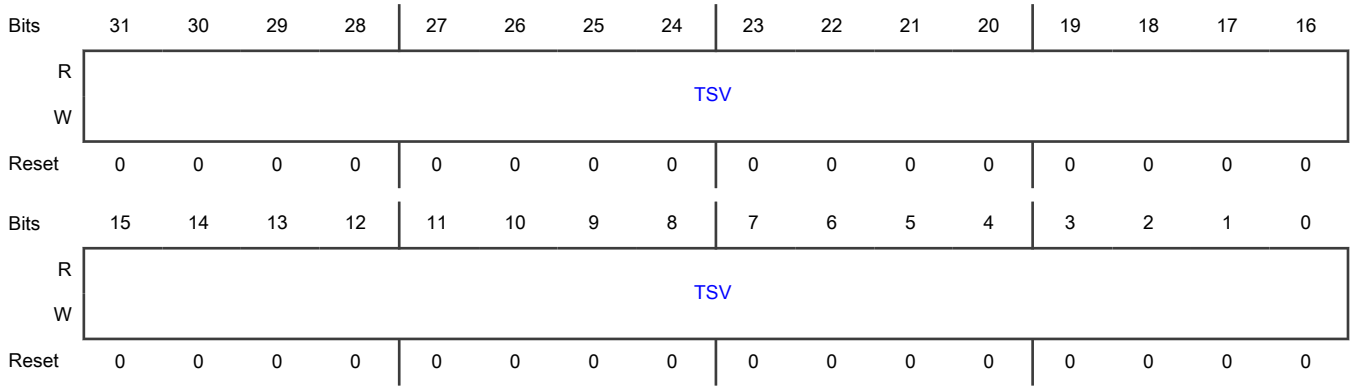
Register	Offset
LDVAL0	100h
LDVAL1	110h
LDVAL2	120h
LDVAL3	130h

Function

Specifies the length of the timeout period in clock cycles.

The value change is visible immediately. The synchronization mechanism allows 0 wait states in this case.

Diagram



Fields

Field	Function
31-0 TSV	Timer Start Value Specifies the starting timer value. The timer counts down until it reaches 0, then sets the interrupt flag and reloads this value. When you write a new value to this register, the timer does not restart with the new value until the current timing period expires. To terminate the current period and start a new period with the new value, you must disable the timer (write 0 to TCTRL*n*[TEN]) and then enable it again (write 1 to TCTRL*n*[TEN]). **NOTE** Because the CPU requires several cycles to service an interrupt, there is a practical limit to the lowest start value for a timer. Setting the value too low may result in a lost interrupt.

68.7.11 Current Timer Value (CVAL0 - CVAL3)

Offset

Register	Offset
CVAL0	104h
CVAL1	114h
CVAL2	124h

RTI Real-time interrupt

Chapter 69
Real Time Clock (RTC)

69.1 Chip-specific RTC information

69.1.1 RTC instances and configuration

The chip contains one instance of RTC (Real Time Clock) timer and API (Autonomous Periodic Interrupt) timer, where both can perform 32-bit comparisons.

The RTC is present in always ON domain, hence available in RUN mode as well as in STANDBY mode. Both RTC and API timers can generate interrupts as well as wakeup from low power modes.

RTC supports a resolution of 1µs with high speed internal oscillator clock (1/48MHz (FIRC) * 48 (RTC counter) = 1µs)

This chip supports seamless RTC operation across functional reset with the clock sources SIRC and SXOSC.

NOTE

SXOSC is not present in K311, thus RTC will run from SIRC clock.

API has the capability to change the Timer compare value (APIVAL) independently without stopping the timer.

API can also be used in conjunction with the Comparator module. In STANDBY mode configuration, the API is configured to generate a START / NEXT type signal to inform the Comparator module that a 'compare' must be carried out.

69.2 Overview

The Real-Time Clock (RTC) is a free-running counter used for time keeping applications. The RTC can be configured to generate an interrupt at a pre-defined interval independent of the mode of operation (run mode or low power mode). If in a low power mode, the RTC interval is reached, the RTC first generates a wakeup and then asserts the interrupt request. The RTC also supports an API function used to generate a periodic wakeup request to exit a low-power mode or an interrupt request.

69.2.1 Block diagram

The following figure shows clock gating for RTC clocks.

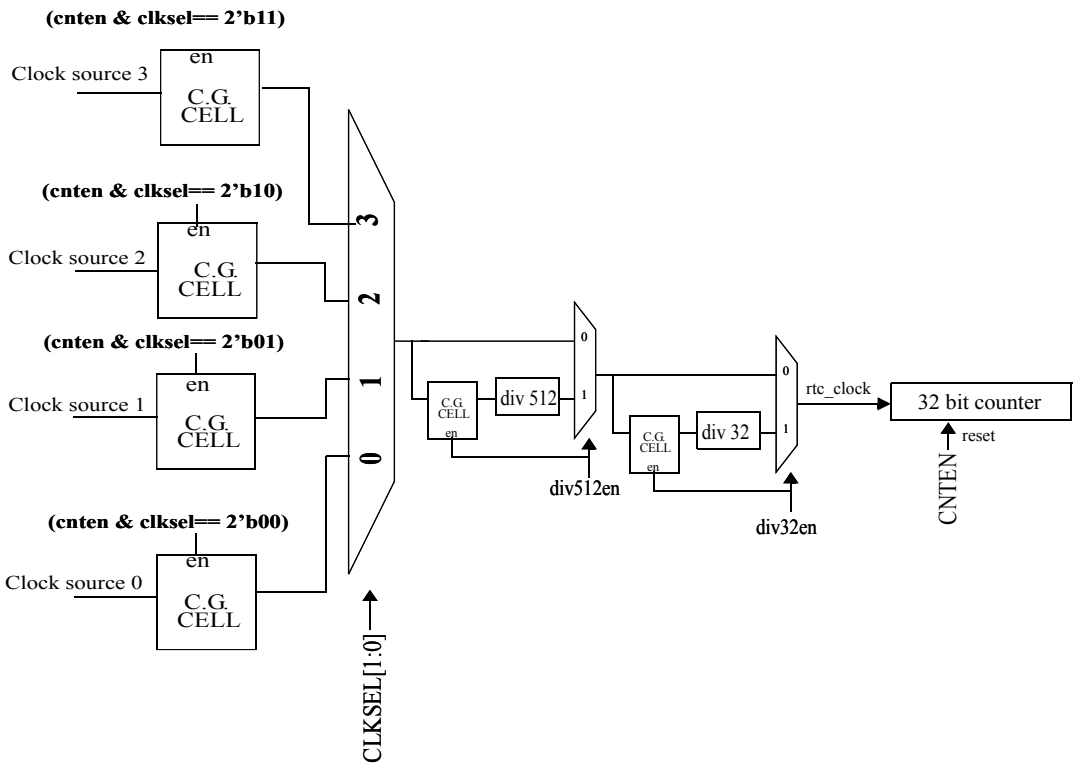

Figure 386. Clock gating for RTC clocks

The following figure shows the block diagram of RTC.

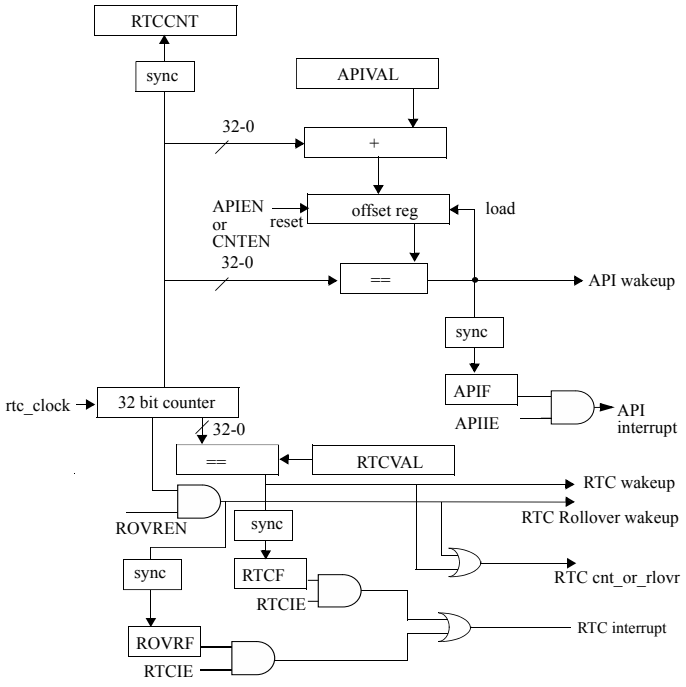

Figure 387. Block diagram

69.2.2 Features

RTC features include:

- 32-bit counter
- Selectable counter clock sources (IRCs and OSCs)
  - Clock source 0
  - Clock source 1
  - Clock source 2
  - Clock source 3
- Optional 512 prescaler and optional 32 prescaler to run the 32 bit counter.
- RTC interrupt with interrupt enable.
- Counter runs in all modes of operation.
- RTC counter is reset when the counter is disabled by software and by reset to RTC block.
- Autonomous periodic interrupt support includes:
  - 32-bit compare value to support range of wakeup intervals/interrupts
  - API logic has a separate enable to support changing compare value while RTC is running
  - API interrupt with interrupt enable
  - Operates in all modes
  - API compare value can be modified while RTC is running
- Optional interrupt for RTC match, API match, and RTC rollover.

69.3 Functional description

69.3.1 RTC

The RTC consists of a 32-bit free running counter enabled with the CNTEN bit (CNTEN, when negated, asynchronously resets the counter and synchronously enables the counter when enabled). After disabling CNTEN, RTCVAL, APIVAL, needs to be written again for desired functionality. The value of the counter may be read via the RTC Count (RTCCNT) register. Note that because of clock synchronization, the RTC Count (RTCCNT) value may represent a previous counter value. The difference between the counter and the read value depends on the ratio of counter clock and bus clock. Maximum possible difference between the two is 6 count values.

The clock source to the counter is selected with the CLKSEL field, which gives four options for clocking the RTC/API. The four clock sources are assumed to be on these:Clock source 0, Clock source 1, Clock source 2, and Clock source 3. The output of the clock mux can be optionally divided by a combination of 512 and 32 to give various count periods for different clock sources. Note that the CNTEN bit should be disabled when the RTC/API clock source is switched.

When the RTC Count (RTCCNT) counter value for counter bits 31-0 match the 32-bit value in the RTCVAL field, then the RTCF interrupt flag bit is set (after proper clock synchronization). If the RTCIE interrupt enable bit is set, then the RTC interrupt request is generated. RTC Compare value register (RTCVAL) register can be written only when INV_RTC bit is clear. Initially INV_RTC=0, and hence RTC Compare value register (RTCVAL) can be written once and hence INV_RTC gets set. This bit can now be cleared only by enabling the RTC counter. After the counter is enabled, RTC Compare value register (RTCVAL) can be written anytime, until RTC is disabled again. RTC Compare value register (RTCVAL) is first synchronized to the RTC clock domain, therefore, if RTC Compare value register (RTCVAL) is updated at the point where a counter match is due to happen in the next 2-3 RTC clocks because of previous RTC Compare value register (RTCVAL), the RTCF flag is set. However, if the RTC Compare value register (RTCVAL) is updated at the point where no counter match is due as per the previous RTC Compare value register (RTCVAL), the RTCF flag is set when the counter matches the new RTC Compare value register (RTCVAL). If there is a match when in the low-power mode, then the RTC first generates a wakeup request to force a wakeup to run mode,and then the RTCF flag is set.

If RTC Compare value register (RTCVAL) is updated just after counter match, new RTC Compare value register (RTCVAL) value should not be within next 6 RTC counter values.

A rollover wakeup and/or interrupt can be generated when the RTC transitions from a count of 0xFFFF_FFFF to 0x0000_0000. The rollover flag is enabled by setting the ROVREN bit. If RTCIE is enabled, an interrupt request is generated for an RTC counter rollover. If system is in low power mode, RTC counter rollover with this bit causes a wakeup from the low-power mode.

Both rollover wakeup and RTC wakeup gets asynchronously de-asserted with disabling of CNTEN.

All the flags and counter values are synchronized with the Bus clock. It is assumed that the Bus clock and RTC clock selected through CLKSEL follows the below relation:

Bus clock >= (1.5 * RTC clock)/(div_factor)

- if both DIV32EN and DIV512EN bits are disabled, div_factor = 1
- if DIV32EN=1 and DIV512EN=0, div_factor = 32
- if DIV32EN=0 and DIV512EN=1, div_factor = 512
- if both DIV32EN and DIV512EN bits are enabled, div_factor = 512*32 = 16384

In case, RTC wakeup's are used as a wakeup source, bus clock (system clock or register interface clock of RTC) should be disabled (to save power in standby mode) after enabling the required wakeup and ensuring sufficient time gap (3-6 bus clock or RTC clock (rtc_clock) cycles, whichever is slower) between bus clock disabling and wakeup event. To ensure writing the register to enable the wakeup, the bus clock must be active, hence it should not be disabled before enabling wakeup. Correct operation is not guaranteed if the specification is not followed.

69.3.2 API functional description

Setting APIEN bit enables the autonomous interrupt function. The 32-bit APIVAL field selects the time interval for triggering an interrupt and/or wakeup event. Because the RTC is a free-running counter, the APIVAL is added to the current count to calculate an offset. When the counter reaches the offset count, an interrupt and/or wakeup request is generated. Then the offset value is recalculated and again re-triggers a new request when the new value is reached. API function is enabled only when CNTEN and APIEN bits are asserted and APIVAL is non-zero. Also APIVAL can be updated anytime. After APIVAL is updated, the first API interrupt is generated according to the previous value. From the second interrupt onwards, the API interrupt is generated with the new APIVAL. When a compare is reached, the APIF interrupt flag bit is set (after proper clock synchronization). If the APIIE interrupt enable bit is set, then the API interrupt request is generated. If there is a match while being in the low-power mode, then the API first generates a wakeup request to force a wakeup into normal operation, and then the APIF flag is set.

When the CNTEN is de-asserted, the API function is reset , though wakeup API is not asynchronously de-asserted with CNTEN. If APIEN is disabled when counter matches the offset APIF can be missed.

69.3.3 Modes of operation

69.3.3.1 Functional mode

There are two functional modes of operation for RTC, normal operation and low-power mode. In normal operation, all RTC registers can be read or written . The RTC/API and associated interrupts are optionally enabled. In low-power mode, the bus interface is disabled. The RTC/API is enabled (if enabled prior to entry into low-power mode).

69.3.3.2 Debug mode

On entering into the debug mode, the RTC counter freezes on the last valid count if the FRZEN is set. On exit from debug mode, counter continues from the frozen value.

69.4 Initialization

Recommended programming flow as follow

1. Program RTCVAL register with the value greater than 4 if RTCF related functionality is required.

2. Program APIVAL register with the value greater than 4 if API functionality is required.
3. Program all fields (as required) of RTC Control (RTCC) register with CNTEN=1. After setting CNTEN field, counter starts running and RTC/API functionality will be active as per the configurations.
4. If RTCVAL or APIVAL needs to be updated during run, check corresponding INV_RTC or INV_API bit is cleared before writing and do meet all the restrictions of the corresponding register.
5. If CLKSEL or DIV32EN or DIV512EN needs to be updated, first update RTC Control (RTCC) register with CNTEN=0 (when all INV_RTC or INV_API are 0) keeping other field values same. Wait for minimum 3 RTC clock cycles so that CNTEN will be synchronized to RTC clock domain. Then write the RTC Control (RTCC) register with new configuration required with CNTEN=1.

69.5 RTC register descriptions

The RTC registers are listed in this section.

NOTE

Address offset - 0x18h should not be accessed by application as corresponding feature/s are not available. Therefore, transfer error will not be generated at this offset.

NOTE

XFR error will be generated when RTCSUPV is accessed in user mode, any other register is accessed in user mode when SUPV bit is set, write attempt is made for RTCCNT register and any register accessed out of address range.

69.5.1 RTC memory map

RTC base address: 4028_8000h

Offset	Register	Width (In bits)	Access	Reset value

69.5.3 RTC Control (RTCC)

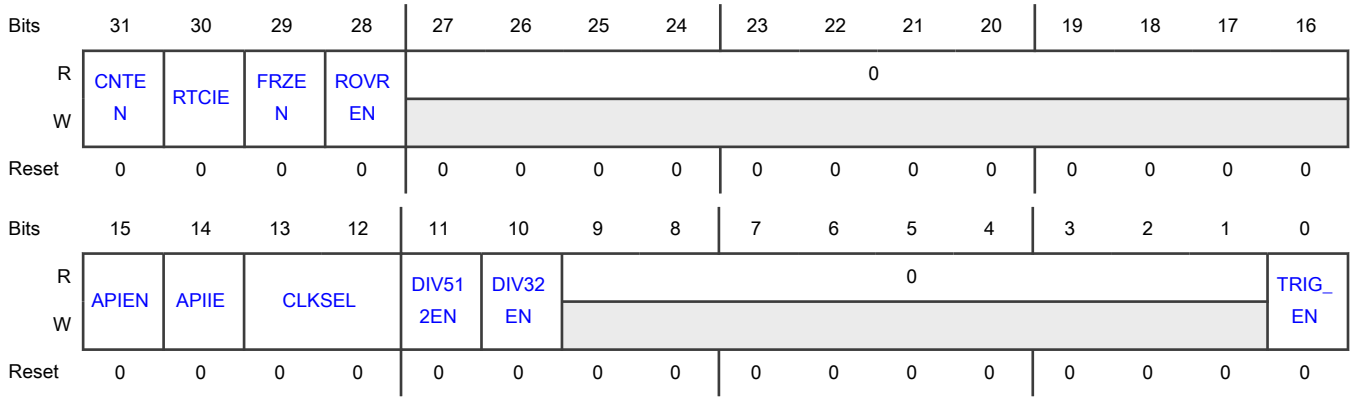
Offset

Register	Offset
RTCC	4h

Function

RTC Control register

Diagram



Fields

Field	Function
31 CNTEN	Counter Enable The CNTEN bit enables the RTC counter. Setting CNTEN bit to 0b has the effect of asynchronously resetting (synchronous reset negation) all the RTC and API logic. This allows RTC configuration and clock source selection to be updated without causing synchronization issues. **NOTE** CNTEN should be disabled when INV_RTC, INV_API are cleared. 0b - Counter disabled 1b - Counter enabled
30 RTCIE	RTC Interrupt Enable The RTCIE bit enables interrupts requests to the system if RTCF is asserted. 0b - RTC interrupts disabled 1b - RTC interrupts enabled
29 FRZEN	Freeze Enable Bit The counter freezes on entering the debug mode on the last valid count value if the FRZEN bit is set. After passing of the debug mode counter starts from the frozen value. This bit should not be changed when debug mode is enabled. 0b - Counter does not freeze in debug mode 1b - Counter freezes in debug mode
28 ROVREN	Counter Roll Over wakeup/Interrupt Enable The ROVREN bit enables wakeup and interrupt requests when the RTC has rolled over from 0xFFFF_FFFF to 0x0000_0000. The RTCIE bit must also be set in order to generate an interrupt from a counter rollover. 0b - RTC rollover wakeup/interrupt disabled 1b - RTC rollover wakeup/interrupt enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-16 —	Reserved
15 APIEN	Autonomous Periodic Interrupt Enable The APIEN bit enables the autonomous periodic interrupt function. Setting this bit to 0b, asynchronously disables API wakeup output of RTC as well. 0b - API disabled 1b - API enabled
14 APIIE	API Interrupt Enable The APIIE bit enables interrupts requests to the system if APIF is asserted. 0b - API interrupts disabled 1b - API interrupts enabled
13-12 CLKSEL	Clock select The CLKSEL[1:0] bits select the clock source for the RTC. CLKSEL may only be updated when CNTEN is 0. The user should ensure that oscillator is enabled before selecting it as a clock source for RTC. **NOTE** Refer the RTC clocking section in the Clocking chapter of this document. 00b - Clock source 0 01b - Clock source 1 10b - Clock source 2 11b - Clock source 3
11 DIV512EN	Divide by 512 enable The DIV512EN bit enables the 512 clock divider. DIV512EN may only be updated when CNTEN is 0. 0b - Divide by 512 is disabled 1b - Divide by 512 is enabled
10 DIV32EN	Divide by 32 enable The DIV32EN bit enables the 32 clock divider. DIV32EN may only be updated when CNTEN is 0. 0b - Divide by 32 is disabled 1b - Divide by 32 is enabled
9-1 —	Reserved
0 TRIG_EN	Trigger enable for Analog Comparator

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit (TRIG_EN) when set will de-assert the wakeup_api on the next RTC clock (required for CMP when bus clock is disabled). **NOTE** If API wakeup is asserted with TRIG_EN set, and bus clock enabled, setting of RTCS[APIF] may be missed.

69.5.4 RTC Status register (RTCS)

Offset

Register	Offset
RTCS	8h

Function

NOTE

W1C has priority over setting of the RTCF, APIF and ROVRF bits, in case both clearing and setting occurs at the same time.

70.1.2 LPSPI HREQ considerations for S32K314, S32K324 and S32K344

It is recommended that the HREQ pin (when PCS[1] is used as HREQ) should get de-asserted before the completion of frame transfer. In case if the HREQ state is still asserted and LPSPI returns to idle state after frame transfer completion, the HREQ state is internally latched and the next data is written to the transmit FIFO without waiting for the next HREQ assertion.

This limitation is present only while using PCS[1] as HREQ and HREQ remains asserted throughout frame transfer. In case of using trigger input as HREQ, there is no issue.

70.2 Overview

LPSPI provides an efficient interface (either as a controller or peripheral) to an SPI bus, which is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing with secure digital cards and LCD displays.

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 438. Updated terms

Updated term	Deprecated term
Controller	Master
Peripheral	Slave

70.2.1 Block diagram

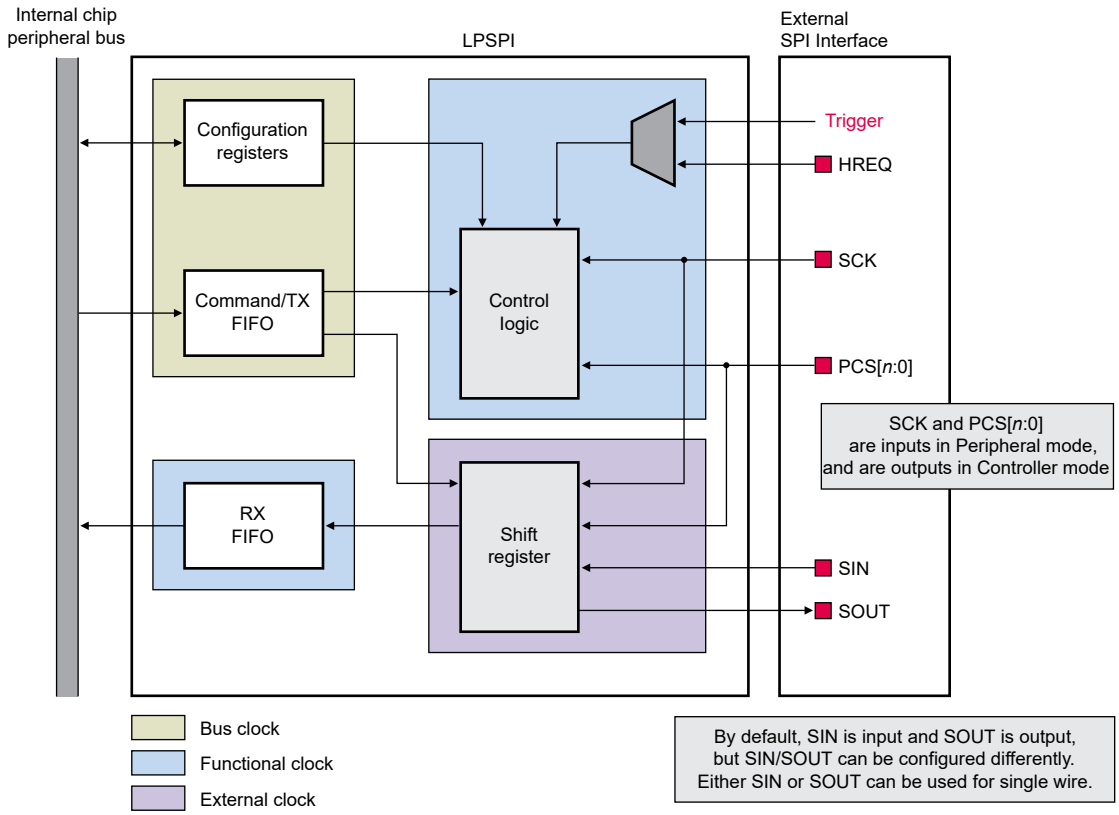

Figure 388. Block diagram

70.2.2 Features

- Minimal CPU overhead, with DMA transmit and receive requests supporting FIFO register accesses
- Support available for 32-bit word size
- Configurable clock polarity and phase
- Support available for 8 peripheral chip selects in Controller mode
- Support available for Peripheral mode
- 4-word transmit and command FIFO
- 4-word receive FIFO
- Flexible timing parameters in Controller mode, including SCK frequency and duty cycle, and delays between PCS and SCK edges
- Continuous transfer option to keep PCS asserted across multiple frames
- Full-duplex transfers that support 1-bit transmit and receive on each clock edge
- Half-duplex transfers that support:
  - 1-bit transmit or receive on each clock edge
  - 2-bit transmit or receive on each clock edge
  - 4-bit transmit or receive on each clock edge
  - 8-bit transmit or receive on each clock edge

- Option to use host request to control the start of an SPI bus transfer

70.3 Functional description

70.3.1 Controller mode

70.3.1.1 Transmit and command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words. You store:

- Transmit data words in the transmit and command FIFO, by writing to Transmit Data (TDR).
- Command words in the transmit and command FIFO, by writing to Transmit Command (TCR).

When a command word is at the top of the transmit and command FIFO, the actions that can occur depend on whether LPSPI is busy or between frames (see TCR[CONT] and TCR[CONTC]). See Table 439 for conditions and possible corresponding actions when a command word is at the top of the transmit and command FIFO.

Table 439. Possible actions when a command word is at the top of the transmit and command FIFO

Condition	Action
LPSPI is enabled and idle.	The command word is pulled from the FIFO, and this command word controls all subsequent transfers.
LPSPI is busy and TCR[CONTC] is 0.	The SPI frame completes at the end of the existing word, ignoring TCR[FRAMESZ]. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with TCR[CONTC] = 0 always terminates the existing transfer regardless of the previous TCR[CONT] value.
LPSPI is busy; the existing TCR[CONT] value is 1 and the new TCR[CONTC] value is 1.	The command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last SCK pulse of the existing frame (based on the value of FRAMESZ), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When TCR[CONTC] = 1, only the lower 24 bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. TCR[CONTC] is ignored when not at a frame boundary, so the frame ends prematurely.

TCR[CONT] = 1 keeps PCS asserted at end of frame, allowing the transfer to continue.

TCR[CONTC] = 1 specifies that this command word must not terminate the existing frame, and the transfer can continue using the new command word.

TCR[CONTC] = 1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary is when the previous command has TCR[CONT] = 1.

You can read the current state of the existing command word from Transmit Command (TCR). It requires at least three LPSPI functional clock cycles for Transmit Command (TCR) to update after you write to it (assuming an empty FIFO), and LPSPI must be enabled (CR[MEN] = 1).

Writing to Transmit Command (TCR) does not initiate an SPI bus transfer, unless TCR[TXMSK] = 1. When TCR[TXMSK] = 1, a new command word is not loaded until the end of the existing frame (based on the value of TCR[FRAMESZ]); at the end of the transfer, TCR[TXMSK] transitions to 0.

In Controller mode, the LPSPI command word in Transmit Command (TCR) controls SPI attributes based on the selections in register fields. See Table 440 for TCR fields and associated functionality related to data transfer.

Table 440. Command word in Controller mode

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
CPOL	Clock polarity	Specifies the polarity of the SCK pin. Any change of CPOL value causes a transition on the SCK pin.	N
CPHA	Clock phase	Specifies the clock phase of the transfer.	N
PRESCALE	Prescaler value	Specifies a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables LPSPI to connect to different peripheral devices at different frequencies.	N
PCS	Peripheral chip select	Specifies which PCS pin asserts for the transfer; the polarity of PCS is static and specified by CFGR1[PCSPOL]. If CFGR1[PCSCFG] = 1, do not select PCS[3:2].	N
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.	Y
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing with devices that organize data as big-endian.	Y
CONT	Continuous transfer	Configures LPSPI for a continuous transfer that keeps PCS asserted between frames (as specified by FRAMESZ). You must write a new command word to cause PCS to negate. Also, this field supports changing the command word at frame size boundaries.	Y
CONTC	Continuing command	Indicates that this is a new command word for the existing continuous transfer. When CONTC = 1, the command word must only be written to the transmit and command FIFO on a frame boundary.	Y
RXMSK	Receive data mask	Masks the receive data and does not store the masked receive data in the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.	Y
TXMSK	Transmit data mask	Masks the transmit data; masked transmit data is not pulled from the transmit FIFO, and the output data pin is 3-stated (unless otherwise configured by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.	Y
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse: • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing with QuadSPI memory devices, and either TXMSK or RXMSK must also be 1. • 8-bit half-duplex transfers are useful for interfacing with OctelSPI memory devices, and either TXMSK or RXMSK must also be 1.	Y

Table continues on the next page...

Table 440. Command word in Controller mode (continued)

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
FRAMESZ	Frame size	Configures the frame size in number of bits equal to (FRAMESZ + 1): • The minimum frame size is 8 bits, or 16 bits for an 8-bit transfer. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remaining bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.	Y

70.3.1.1.1 SPI bus transfers

LPSPI initiates an SPI bus transfer when all these conditions are true:

- Data is written to the transmit FIFO.
- The HREQ pin is asserted (or the HREQ function is disabled).
- LPSPI is enabled.

To perform the SPI bus transfer, LPSPI uses the attributes configured in Transmit Command (TCR) and the timing parameters defined in Clock Configuration (CCR).

The SPI bus transfer ends after the number of bits indicated by the value of FRAMESZ have been transferred (provided CONT = 0), or at the end of a word when a new transmit command word is at the top of the transmit and command FIFO. When LPSPI is disabled, the SPI bus transfers end after the transmit FIFO is empty and LPSPI is idle.

The HREQ input is only checked when PCS is negated.

70.3.1.1.2 Circular FIFO

The transmit and command FIFO supports a circular FIFO feature. This feature enables the LPSPI controller to (periodically) repeat a short data transfer that fits within the transmit and command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled (CFGR0[CIRFIFO] = 1), the current state of the FIFO read pointer is saved and the status flags are not updated. After the FIFO is empty and LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit and command FIFO are not permanently pulled from the FIFO when Circular FIFO mode is enabled.

70.3.1.2 Receive FIFO and data match

The receive FIFO stores received data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of being stored in the receive FIFO:

- Received data is written to the receive FIFO when the last bit of the word is sampled.
- If the transmit FIFO is empty during a multiple-word or continuous transfer, then the receive data is written to the receive FIFO before the transfer stalls (assuming CFGR1[NOSTALL] = 0) while waiting for new transmit data or for a command word to be written.

LPSPI provides a receive data match function that can match received data against one of the two words in DMR0 and DMR1, or against a masked data word. You can also configure the received data match function to compare only the first one or two received data words since the start of the frame:

- Received data that is already discarded because of TCR[RXMSK] cannot cause the data match flag to set, and delays the receive data match on the first received data word, until all discarded data is received.
- You can configure the receive data match function to discard all received data until a data match is detected, using CFGR0[RDMO].
- After a receive data match, to allow all subsequent data to be received, write 0 to CFGR0[RDMO], and then write 0 to SR[DMF].

70.3.1.3 Timing parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the selection specified in TCR[PRESCALE]. Although you cannot change Clock Configuration (CCR) when LPSPI is busy, to support interfacing with different peripheral devices at different frequencies, you can change the TCR[PRESCALE] selection between SPI bus transfers by using Transmit Command (TCR).

NOTE

The minimum value shown in Table 441 is the minimum counter value, but the values of Clock Configuration (CCR) must also satisfy the data sheet specs based on the LPSPI functional clock frequency and prescaler value.

Table 441. Timing parameters

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Minimum value	Maximum value
Field	Name			
SCKSET	SCK setup phase	Configures the SCK setup phase to (SCKSET + 1) cycles. The setup phase is the SCK high period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK low period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
SCKHLD	SCK hold phase	Configures the SCK hold phase to (SCKHLD + 1) cycles. The hold phase is the SCK low period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK high period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
PCSPCS	PCS-to-PCS delay	Configures the minimum delay between PCS negation and the next PCS assertion to (PCSPCS + PCSPCS + 2) cycles. When the command word is updated between transfers, there is a minimum of (PCSPCS + 1) cycles between the command word update and any change on PCS pins.	0 (2 cycles)	255 (512 cycles)
SCKSCK	SCK-to-SCK delay	Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (SCKSCK + 1) cycles. This is useful when the external peripheral	0 (1 cycle)	255 (256 cycles)

Table continues on the next page...

Table 441. Timing parameters (continued)

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Minimum value	Maximum value
Field	Name			
		requires a large delay between different words of an SPI bus transfer.		
PCSSCK	PCS-to-SCK delay	Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.	0 (1 cycle)	255 (256 cycles)
SCKPCS	SCK-to-PCS delay	Configures the minimum delay between the last SCK edge and the PCS negation to (SCKPCS + 1) cycles.	0 (1 cycle)	255 (256 cycles)

Figure 389 shows the timing settings controlled by:

- TCR[CPHA]
- TCR[CPOL]
- CCR[SCKPCS]
- CCR[PCSSCK]
- CCR1[SCKSET]
- CCR1[SCKHLD]

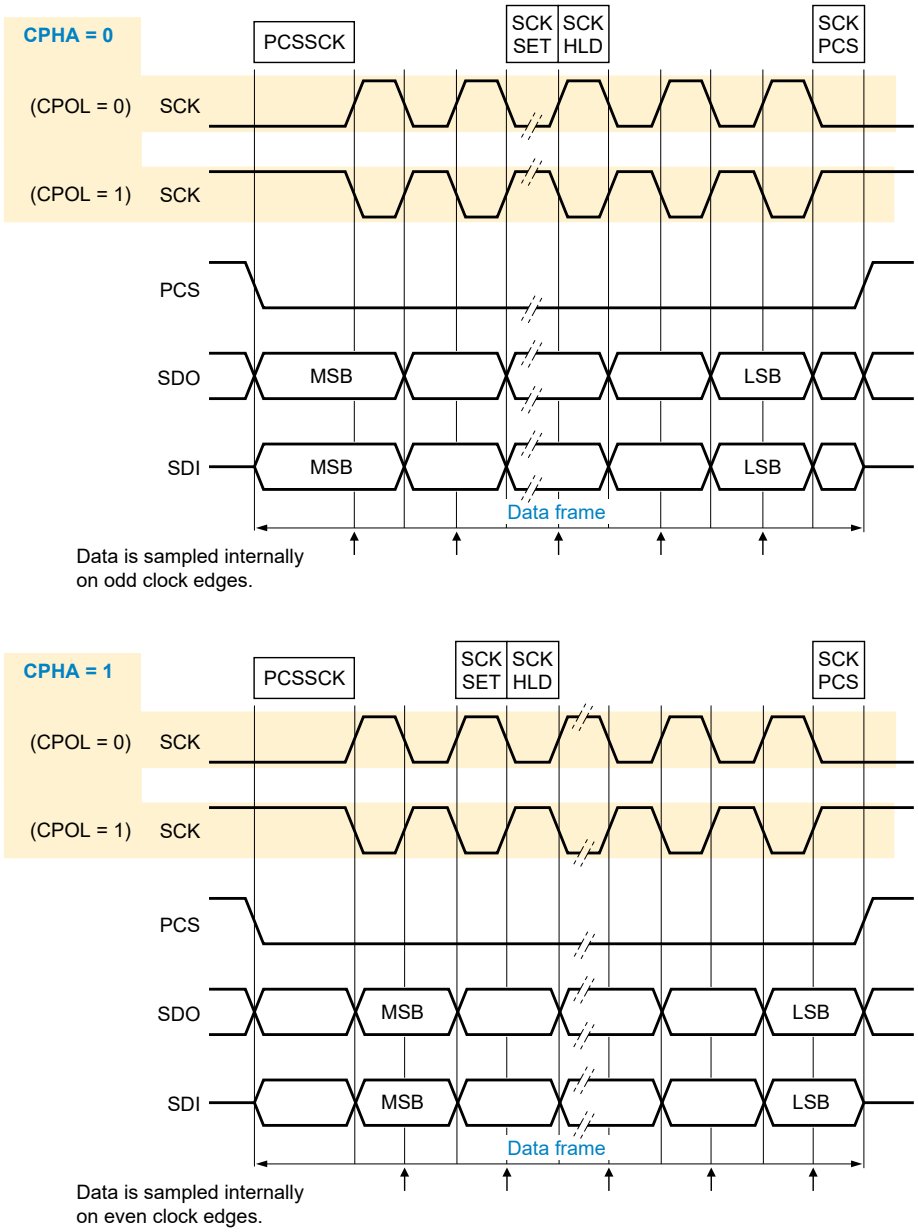

Figure 389. Clock phase (TCR[CPHA]) timing diagram example

To configure for a baud rate of 10 MHz with 50/50 duty cycle and with a functional clock frequency of 100 MHz, use the following settings:

- CCR1[SCKSET] = 0x4 (5 cycles)
- CCR1[SCKHLD] = 0x4 (5 cycles)
- CCR1[PCSPCS] = 0x8 (10 cycles)
- CCR1[SCKSCK] = 0x4 (5 cycles)
- CRR[PCSSCK] = 0x4 (5 cycles)
- CRR[SCKPCS] = 0x4 (5 cycles)
- TCR[PRESCALE] = 0x0 (divide by 1)

70.3.1.4 Pin configuration

Following are the pin configuration settings for half-duplex transfers:

- To swap directions or to support half-duplex transfers on the same pin, you can configure the SIN and SOUT pins using CFGR1[PINCFG].
- To specify whether an output data pin (SOUT, for example) 3-states when PCS is negated, or if the output data pin retains the last value, use CFGR1[OUTCFG].
- When configuring half-duplex transfers, you must configure the output data pins to 3-state when PCS is negated (CFGR1[OUTCFG] = 1).
- When performing half-duplex 2-bit transfers, you can write any value to CFGR1[PCSCFG].
- When performing half-duplex 4-bit transfers, you must write 1h to CFGR1[PCSCFG].

70.3.1.5 Clock loopback

Configure the LPSPI controller to use one of the following clocks to sample the input data:

- The SCK output clock
- A delayed version of the SCK output clock

The delayed version of the SCK is chosen by the SCK pin output delay, plus the SCK pin input delay, and is selected by writing 1 to CFGR1[SAMPLE]. Enabling the loopback version of the SCK pin can improve the setup time of the input data from the peripheral.

See the chip data sheet for the specific input setup time in Controller Loopback mode.

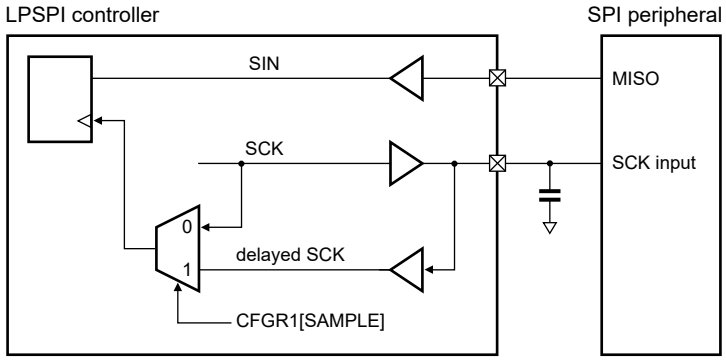

Figure 390. Clock loopback

70.3.2 Peripheral mode

LPSPI Peripheral mode:

- Uses the same shift register and logic that Controller mode uses.
- Does not use Clock Configuration (CCR).
- Requires Transmit Command (TCR) to remain static (unchanged) during SPI bus transfers.

70.3.2.1 Transmit and command FIFO commands

You must initialize Transmit Command (TCR) before enabling LPSPI in Peripheral mode, although this register is not updated until after LPSPI is enabled. After LPSPI is enabled, you must make changes to this register only when LPSPI is idle. In Peripheral mode, the LPSPI command word in this register controls SPI attributes. Before the PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag sets.

Table 442. Command word in Peripheral mode

Transmit Command (TCR)		Description
Field	Name	
CPOL	Clock polarity	Specifies the polarity of the external SCK input.
CPHA	Clock phase	Specifies the clock phase of transfer.
PRESCALE	Prescaler value	Specifies the LPSPI functional clock prescaler.
PCS	Peripheral chip select	Specifies which PCS is used. The polarity of PCS is static and configured by CFGR1[PCSPOL]. If CFGR1[PCSCFG] is not equal to zero, then do not select the PCS[3:2] pins.
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing with devices that organize data as big-endian.
CONT	Continuous transfer	When continuous transfer is selected in Peripheral mode, after the number of bits indicated by FRAMESZ are transferred, LPSPI passes through and transmits the received data until the next PCS negation. Whatever is shifted in on the receive data is shifted out as transmit data considering that there is a 32-bit shift register.
CONTC	Continuing command	When the continuing command is enabled in Peripheral mode, after the number of bits indicated by FRAMESZ are transferred, RXMSK is considered equal to 1 and TXMSK is considered equal to 0 until the next PCS negation. CONTC can be used to change the direction of a transfer after the number of bits indicated by FRAMESZ.
RXMSK	Receive data mask	Masks the receive data; LPSPI does not store masked receive data in the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.
TXMSK	Transmit data mask	Masks the transmit data so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is 3-stated (unless otherwise specified in CFGR1[OUTCFG]). This option is useful for half-duplex transfers.
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse: • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing with QuadSPI memory devices, and at least either TCR[TXMSK] or TCR[RXMSK] must be 1. • 8-bit half-duplex transfers are useful for interfacing with OctelSPI memory devices, and at least either TCR[TXMSK] or TCR[RXMSK] must also be 1.
FRAMESZ	Frame size	Specifies the frame size in number of bits equal to (FRAMESZ + 1): • The minimum frame size is 8 bits, or 16 bits for an 8-bit parallel transfer. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contain the remainder bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.

70.3.2.2 Receive FIFO and data match

The receive FIFO stores receive data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of storing the received data in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of the two words in DMR0 and DMR1 or against a masked data word. You can also configure the data match function to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded because TCR[RXMSK] = 1 cannot cause the data match to set, and delays the match on the first received data word, until all discarded data is received.
- By using CFGR0[RDMO], you can also configure the receiver match function to discard all received data until a data match is detected.
- After a receive data match, to allow all subsequent data to be received, first write 0 to CFGR0[RDMO], then clear SR[DMF].

70.3.2.3 Partial received word

When the PCS pin deasserts and the receive shift register shifts in a partial word, you can configure the receive shift register to either discard the partial word or to store it in the receive FIFO. You must specify this using CFGR1[PARTIAL].

A partial word is defined as less than TCR[FRAMESZ] bits (when TCR[FRAMESZ] is equal or less than 32 bits, or it is the last word in a multi-word frame) or less than 32 bits (when TCR[FRAMESZ] is greater than 32 bits and not the last word in a multi-word frame).

A single-bit frame is not supported. A partial received word of 1 bit is supported, but a partial received frame of 1 bit is not supported.

70.3.2.4 Clocked interface

LPSPI supports interfacing with external controllers that provide only clock and data pins (PCS is not required). This interface requires:

- Writing 1 to TCR[CPHA] (data is changed on the leading edge of SCK and captured on the following edge).
- Configuring the PCS input to be always asserted (CFGR1[PCSPOL*n*] = 1). For example, to configure PCS[0] to be always asserted, write 1 to PCSPOL[0], and do not configure PCS[0] in the pin muxing. The chip-level drives PCS to a certain value (ideally 1); you could use CFGR1[PCSPOL*n*] to invert that value.
- Writing 1 to CFGR1[AUTOPCS] to enable automatic PCS generation. When CFGR1[AUTOPCS] = 1, a minimum of four LPSPI functional clock cycles (divided by the selection specified in TCR[PRESCALE]) is required between the last SCK edge of one word and the first SCK edge of the next word.

70.3.3 Debug mode

Table 443. Debug mode

Chip mode	LPSPI operation
Debug (the core is in Debug or Halted mode)	Can continue operating in Debug mode, if CR[DBGEN] = 1

70.3.4 Clocking

Table 444. LPSPI clocks

Type of clock	Description
Functional	• Asynchronous to the bus clock. • If the LPSPI functional clock remains enabled in low-power modes, then LPSPI can perform SPI bus transfers and low-power wakeups in both Controller and Peripheral modes. • LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least two times faster than the SPI external clock frequency (SCK).
External	• The LPSPI shift register is clocked directly by the SCK clock. • How the SCK clock is generated or supplied depends on the mode (Controller or Peripheral): — In Controller mode, the SCK clock is generated internally. — In Peripheral mode, the SCK clock is supplied externally.
Bus	The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs.

See the chip-specific LPSPI information for more.

70.3.5 Reset

Table 445. LPSPI resets

Type of reset	Description
Chip	Resets the LPSPI logic and registers to their default states.
Software	• Resets the LPSPI logic and registers to their default states, except for the Control register. • The LPSPI software reset is controlled using CR[RST].
FIFO	• Resets the transmit and command FIFO and the receive FIFO. • CR[RTF] and CR[RRF] are write-only. • After being reset, FIFO is empty.

70.3.6 Interrupts and DMA requests

The following table lists sources (status flags) that can generate LPSPI interrupts and LPSPI transmit and receive DMA requests.

Table 446. Interrupts and DMA requests

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
TDF	Transmit data flag	Indicates that data can be written to transmit FIFO, as configured by the transmit FIFO watermark, FCR[TXWATER].	Y	TX	Y

Table continues on the next page...

Table 446. Interrupts and DMA requests (continued)

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
RDF	Receive data flag	Indicates that data can be read from the receive FIFO, as configured by the receive FIFO watermark, FCR[RXWATER].	Y	RX	Y
WCF	Word complete flag	Indicates that the word is complete and the last bit of the word has been sampled.	Y	N	Y
FCF	Frame complete flag	Indicates that the frame is complete and PCS is deasserted.	Y	N	Y
TCF	Transfer complete flag	Indicates that transfer is complete, PCS is deasserted, and the transmit and command FIFO is empty.	Y	N	Y
TEF	Transmit error flag	Indicates a transmit and command FIFO underrun. In Controller mode, when CFGR1[NOSTALL] = 0 (transfers stall when transmit FIFO is empty), TEF cannot be set.	Y	N	Y
REF	Receive error flag	Indicates a receive FIFO overflow. In Controller mode, when CFGR1[NOSTALL] = 0 (transfers stall when receive FIFO is full), REF cannot be set.	Y	N	Y
DMF	Data match flag	Indicates that the received data matches the configured data match value.	Y	N	Y
MBF	Module busy flag	Indicates that LPSPI is busy performing an SPI bus transfer.	N	N	N

70.3.6.1 DMA support registers

To support efficient DMA transfers to the transmit and control FIFO, an alias register supports 32-bit write access to the Transmit Command (TCR) and an alias region supports incrementing 32-bit write accesses to the Transmit Data (TDR).

- Transmit Command Burst (TCBR) is a 32-bit alias register for writing to TCR.
- Transmit Data Burst (TDBR0 - TDBR127) is a 512-byte alias region that supports writing to the TDR.

The burst alias locations are contiguous. A DMA transfer can start by writing to the TCBR register to initialize the transfer and then increment into the TDBR region without changing the DMA transfer size. The alias registers can also be used by the DMA to perform burst transfers when accessing the transmit FIFO.

The transmit FIFO prevents writes that overflow the FIFO, but this prevention does not signal an error. Do not perform writes to the TDBR unless there is sufficient room in the transmit FIFO.

Receive Data Burst (RDBR0 - RDBR127) is a 512-byte alias region that supports reading the Receive Data. This can be used by the DMA to perform burst transfers when accessing the receive FIFO.

70.3.7 Peripheral triggers

The connection of the LPSPI peripheral triggers with other peripherals depends on the device that is used.

Table 447. Peripheral triggers

Type of trigger	Description	Additional information
Frame output	The frame output trigger: • Asserts at the end of each frame (when PCS deasserts). • Remains asserted for one cycle of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE].	LPSPI generates two output triggers that can be connected to other peripherals on the chip.
Word output	The word output trigger: • Asserts at the end of each received word. • Remains asserted for one cycle of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE].	
Input	To control the start of an LPSPI bus transfer, the LPSPI input trigger can be selected instead of the HREQ input: • The LPSPI input trigger is synchronized, and must assert for at least two cycles of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE] so that the input trigger can be detected. • When LPSPI is busy, the HREQ input (and therefore the LPSPI input trigger) is ignored. • When LPSPI is busy, both the HREQ and LPSPI input triggers are ignored. They are used to start a new transfer when LPSPI is idle.	

70.4 External signals

Table 448. External signals

Signal	Name	Description	I/O
SCK	Serial clock	• Input in Peripheral mode • Output in Controller mode	I/O
PCS[0]	Peripheral chip select	• Input in Peripheral mode • Output in Controller mode	I/O
PCS[1]/HREQ	Peripheral chip select or host request	Host request pin is selected when CFGR0[HREN] = 1 and CFGR0[HRSEL] = 0: • Input in either Peripheral mode or when used as controller host request • Output in either Controller mode or when used as peripheral host request	I/O
PCS[2]/DATA[2]	Peripheral chip select or data pin 2 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Peripheral mode • Output in Controller mode When CFGR1[PCSCFG] = 1:	I/O

Table continues on the next page...

Table 448. External signals (continued)

Signal	Name	Description	I/O
		• Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	
PCS[3]/DATA[3]	Peripheral chip select or data pin 3 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Peripheral mode • Output in Controller mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[4]/DATA[4]	Peripheral chip select or data pin 4 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Peripheral mode • Output in Controller mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[5]/DATA[5]	Peripheral chip select or data pin 5 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Peripheral mode • Output in Controller mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[6]/DATA[6]	Peripheral chip select or data pin 6 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Peripheral mode • Output in Controller mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O

Table continues on the next page...

Table 448. External signals (continued)

Signal	Name	Description	I/O
PCS[7]/DATA[7]	Peripheral chip select or data pin 7 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Peripheral mode • Output in Controller mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
SOUT/DATA[0]	Serial data output	Can be configured as serial data input signal (used as data pin 0 in half-duplex parallel data transfers)	I/O
SIN/DATA[1]	Serial data input	Can be configured as serial data output signal (used as data pin 1 in half-duplex parallel data transfers)	I/O

70.5 Initialization

This module does not require initialization.

70.6 Memory map and registers

NOTE

- Writing to a read-only register or reading a write-only register can cause bus errors.
- LPSPI does not check values programmed in registers for validity, so you must take care to write valid values only.

70.6.1 LPSPI register descriptions
